On-Chip Debug Emulator with Programming Function

[MEMO]

MINICUBE is a registered trademark of NEC Electronics Corporation in Japan and Germany and Germany or a trademark in the United States of America.

Windows is either a registered trademarks or a trademark of Microsoft Corporation in the United States and/or other countries.

PC/AT is a trademark of International Business Machines Corporation.

- The information in this document is current as of April 2006. The information is subject to change
 without notice. For actual design-in, refer to the latest publications of NEC Electronics data sheets or
 data books, etc., for the most up-to-date specifications of NEC Electronics products. Not all
 products and/or types are available in every country. Please check with an NEC Electronics sales
 representative for availability and additional information.
- No part of this document may be copied or reproduced in any form or by any means without the prior
 written consent of NEC Electronics. NEC Electronics assumes no responsibility for any errors that may
 appear in this document.
- NEC Electronics does not assume any liability for infringement of patents, copyrights or other intellectual property rights of third parties by or arising from the use of NEC Electronics products listed in this document or any other liability arising from the use of such products. No license, express, implied or otherwise, is granted under any patents, copyrights or other intellectual property rights of NEC Electronics or others.
- Descriptions of circuits, software and other related information in this document are provided for illustrative
 purposes in semiconductor product operation and application examples. The incorporation of these
 circuits, software and information in the design of a customer's equipment shall be done under the full
 responsibility of the customer. NEC Electronics assumes no responsibility for any losses incurred by
 customers or third parties arising from the use of these circuits, software and information.
- While NEC Electronics endeavors to enhance the quality, reliability and safety of NEC Electronics products, customers agree and acknowledge that the possibility of defects thereof cannot be eliminated entirely. To minimize risks of damage to property or injury (including death) to persons arising from defects in NEC Electronics products, customers must incorporate sufficient safety measures in their design, such as redundancy, fire-containment and anti-failure features.
- NEC Electronics products are classified into the following three quality grades: "Standard", "Special" and
 "Specific".
 - The "Specific" quality grade applies only to NEC Electronics products developed based on a customer-designated "quality assurance program" for a specific application. The recommended applications of an NEC Electronics product depend on its quality grade, as indicated below. Customers must check the quality grade of each NEC Electronics product before using it in a particular application.
 - "Standard": Computers, office equipment, communications equipment, test and measurement equipment, audio and visual equipment, home electronic appliances, machine tools, personal electronic equipment and industrial robots.
 - "Special": Transportation equipment (automobiles, trains, ships, etc.), traffic control systems, anti-disaster systems, anti-crime systems, safety equipment and medical equipment (not specifically designed for life support).
 - "Specific": Aircraft, aerospace equipment, submersible repeaters, nuclear reactor control systems, life support systems and medical equipment for life support, etc.

The quality grade of NEC Electronics products is "Standard" unless otherwise expressly specified in NEC Electronics data sheets or data books, etc. If customers wish to use NEC Electronics products in applications not intended by NEC Electronics, they must contact an NEC Electronics sales representative in advance to determine NEC Electronics' willingness to support a given application.

(Note)

- (1) "NEC Electronics" as used in this statement means NEC Electronics Corporation and also includes its majority-owned subsidiaries.
- (2) "NEC Electronics products" means any product developed or manufactured by or for NEC Electronics (as defined above).

General Precautions for Handling This Product

- 1. Circumstances not covered by product guarantee
 - If the product was disassembled, altered, or repaired by the customer
 - If it was dropped, broken, or given another strong shock
 - Use at overvoltage, use outside guaranteed temperature range, storing outside guaranteed temperature range
 - If power was turned on while the USB cable or connection to the target system was in an unsatisfactory state
 - If the cable of the USB cable, the target cable, or the like was bent or pulled excessively
 - If the product got wet
 - If this product is connected to the target system when there is a potential difference between the GND of this product and GND of the target system.
 - If the connectors or cables are plugged/unplugged while this product is in the power-on state.
 - If excessive load is applied to the connectors or sockets.
 - If a metal part of the interface connector or another such part comes in contact with an electrostatic charge
 - If specifications other than those specified are used for the USB port

2. Safety precautions

- The product may become hot depending on the status of use. Be careful of low temperature burns and other dangers due to the product becoming hot.
- Be careful of electrical shock. There is a danger of electrical shock if the product is used as described above in 1 Circumstances not covered by product guarantee.
- Do not use a device that was used for on-chip debugging as the official product.

INTRODUCTION

Target Readers This manual is intended for users who wish to perform debugging using the

QB-MINI2 (generic name: MINICUBE2).

The readers of this manual are assumed to be familiar with the device functions

and usage, and to have knowledge of debuggers and flash programming.

Purpose This manual is intended to give users an understanding of the basic

specifications and correct use of MINICUBE2.

Organization This manual includes the following sections.

Overview

• Names and functions of hardware

Usage for each device

How to Read This Manual It is assumed that the readers of this manual have general knowledge in the

fields of electrical engineering, logic circuits, and microcontrollers.

This manual describes the basic setup procedures.

To understand the basic specifications and usages of MINICUBE2

→ Read this manual according to the **CONTENTS**.

To know the manipulations, command functions, and other software-related settings of MINICUBE2

ightarrow See the user's manual of the debugger to be used.

Conventions Note: Footnote for item marked with Note in the text

Caution: Information requiring particular attention

Remark: Supplementary information

Numeric representation: Binary ... xxxx or xxxxB

Decimal ... xxxx

Hexadecimal ... xxxxH

Prefix indicating power of 2 (address space, memory capacity):

K (kilo): $2^{10} = 1,024$

M (mega): $2^{20} = 1,024^2$

Terminology

The meanings of the terms used in this manual are as follows.

Term	Meaning
MINICUBE2	Generic name of QB-MINI2
Target device	This is the device to be emulated.
Target system	This is the system to be debugged (user-created system).
	It includes software and hardware created by the user.
OCD unit	OCD is an abbreviation of On-Chip Debug
	The OCD unit means the debug function block embedded in the target
	device.
Firmware	Program embedded in the device for controlling MINICUBE2
QB-Programmer	GUI software used to perform flash programming

CHAPTER 1 OVERVIEW

MINICUBE2 is an on-chip debug emulator with flash programming function, which is used for debugging and programming a program to be embedded in on-chip flash memory microcontrollers.

1.1 Features

On-chip debugging

Can debug with the target microcontroller connected to the target system.

Flash memory programming

Can write programs to the on-chip flash memory of microcontrollers.

USB connection

Can be connected to the host machine via USB interface 2.0 or 1.1.

Since MINICUBE2 operates on power supplied via USB, an external power supply is unnecessary.

Variety of supported devices and expandability

MINICUBE2 supports a wide variety of NEC Electronics 8- to 32-bit on-chip flash memory microcontrollers. More devices can be supported by upgrading firmware embedded in MINICUBE2.

Self-testing function

MINICUBE2 has a self-testing function, which is used to detect faults in MINICUBE2 and perform maintenance.

1.2 Notes Before Using MINICUBE2

Chapters 1 and 2 present an overview and the basic specifications of MINICUBE2, and the following chapters provide separate descriptions for the target devices and the purpose of use. To utilize this manual effectively, refer to the following table and see the relevant chapter for your target device and purpose of use.

1.3 Supported Devices

Access the following MINICUBE2 information site or refer to the document for details on the devices that support debugging and flash programming with MINICUBE2. The document describes the development tools that are required as the support conditions, serial interface and operating precautions, so be sure to read the document, in addition to this manual.

• MINICUBE2 information site

URL: http://www.necel.com/micro/english/product/sc/allflash/minicube2.html

Remark This website just posts the supported target devices. For details on the development tools that are required as the support conditions, refer to the document below.

1.4 Hardware Specifications

This section describes the MINICUBE2 hardware specifications.

The specifications related to the on-chip debug and flash memory programming functions are described in the following chapters.

Table 1-2. Hardware Specifications

Classification	Item	Specifications			
MINICUBE2	Operating power supply	Supplied via USB interface (5 V)			
	Operating clock	Clock mounted in MINICUBE2			
	Operating environment	Temperature: ±0 to +40°C			
	conditions	Humidity: 10 to 80% RH (no condensation)			
	Storage environment	Temperature: –15 to +60°C			
	conditions	Humidity: 10 to 80% RH (no condensation)			
	External dimensions	48 × 48 × 13.9 mm			
	Weight	Approximately 40 g			
Host machine interface	Target host machine	PC98-NX Series, IBM PC/AT TM compatibles			
	Target OS	Windows TM 98, Windows Me, Windows 2000, Windows XP			
	USB	2.0 (1.1 compatible)			
	USB cable	2 m			
	Current consumption	500 mA max.			
Target interface	Target cable length	16-pin cable: 10 cm			
		10-pin cable: 10 cm			
	Supported connector	2.54 mm pitch general-purpose connector			
	Supply voltage	3.1 V (typ.) or 5.0 V (typ.)			
	Supply current	100 mA max.			
	Current consumption	8 mA (typ.)			
	Voltage range	1.65 to 5.5 V			

CHAPTER 2 NAMES AND FUNCTIONS OF HARDWARE

This chapter describes the part names and functions of MINICUBE2 and its accessories.

The part names described in this chapter are used throughout this document. This chapter provides an overview of the various functions. Reading it through, the reader will gain a basic grasp of MINICUBE2 and the self-check board that will facilitate reading of subsequent chapters. While reading this chapter, also check if the hardware has a defect.

2.1 Names of Supplied Hardware

Figure 2-1 shows the names of hardware supplied with MINICUBE2.

Figure 2-1. Names of Supplied Hardware

USB cable

10-pin target cable

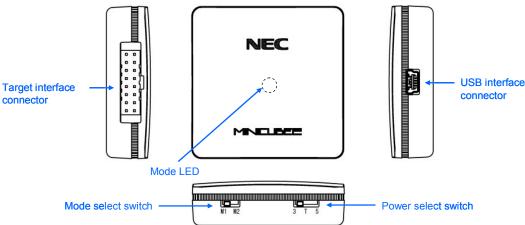

78K0-OCD board (A 20 MHz oscillator mounted)

2.2 Part Names and Functions of MINICUBE2

Figure 2-2 shows the part names of the MINICUBE2 main unit. For their functions, refer to (1) to (5) below.

Figure 2-2. Part Names of MINICUBE2

(1) Mode select switch

This switch is used to select the target device. Table 2-1 describes the setting details. This switch is set to "M2" at shipment.

Table 2-1. Description of Mode Select Switch

Setting	Description
M1	Sets 78K0S Series as target device
M2	Sets V850 or 78K0 Series as target device (factory setting)

(2) Power select switch

This switch is used to set the power supplied to the target system. Table 2-2 describes the setting details. This switch is set to "3" at shipment.

Caution Do not change the switch setting while the USB cable is connected.

Table 2-2. Setting of Power Select Switch

Setting	Description
3	3 V is supplied from MINICUBE2 to the target system Note. (Factory setting)
	The supplied power is fed back to MINICUBE2 and used only for power detection.
5	5 V is supplied from MINICUBE2 to the target system Note.
	The supplied power is fed back to MINICUBE2 and used only for power detection.
Т	Power supply of the target system is used.
	MINICUBE2 only detects the power for the target system.

Note The maximum rating of the current is 100 mA, so do not use MINICUBE2 with the target system with the higher current rating. The power is always supplied after MINICUBE2 is connected to the host machine.

(3) USB interface connector

This is a connector used to connect MINICUBE2 with the host machine, via a USB cable.

A USB 2.0 compliant mini-B connector (UX60A-MB-5ST: Made by Hirose Electric Co., Ltd.) is employed.

(4) Target interface connector

This is a connector used to connect MINICUBE2 with the target system, via a 16-pin target cable. Connect the 78K0-OCD board for debugging a 78K0 microcontroller. To prevent the 78K0-OCD board from being inserted by mistake, pin 11 is removed at shipment.

Since this connector is compatible with 16-core 2.54 mm pitch general-purpose connectors (female), a commercially available cable can be substituted.

(5) Mode LED

The appearance of the mode LED changes according to the status of hardware and software, as shown in Table 2-3.

Table 2-3. Mode LED Status

-							
Mode LED	Appearance	Description					
Color		USB	Target VDD	Software Operation Status			
		Connection	Detection				
_	Extinguished	Not	Not detected	Not yet started			
		connected					
White	Flashing	Connected	Not detected	Not yet started			
	Glowing		Detected	Not yet started			
Blue	Glowing			A V850 Series debugger has been started and CPU is in the			
				break mode.			
	Flashing			A V850 Series debugger has been started and the CPU is			
				running, or a program is being downloaded.			
Orange	Glowing			A 78K0 Series debugger has been started and the CPU is in			
				the break mode.			
	Flashing			A 78K0 Series debugger has been started and the CPU is			
				running, or a program is being downloaded.			
Green	Glowing			A 78K0S Series debugger has been started and the CPU is			
				in the break mode. The QB-Programmer has been started			
				and is waiting for execution processing.			
				Alternatively, execution processing has been completed.			
	Flashing			A 78K0S Series debugger has been started and the CPU is			
				running, or a program is being downloaded.			
Yellow	Flashing			A command from the QB-Programmer is being executed for			
				the flash memory			
Red	Glowing			A command from the QB-Programmer is ended abnormally			
			(results in error)				
	The illumination mode is entered when MINICUBE2 is connected to a USB interface and 15						
Illumination	nation seconds or longer have elapsed. This mode is also entered when the debugger is terminate			d. This mode is also entered when the debugger is terminated			
		normally.					

2.3 Part Names and Functions of 78K0-OCD Board

The 78K0-OCD board is used for debugging a 78K0 microcontroller (not used for flash programming). Figure 2-3 illustrates the external view of the 78K0-OCD board. The name of each part is printed on the 78K0-OCD board. For each function, refer to (1) to (4), below.

SS-77019-2[e] 78KO OCD

GLK1

ONI

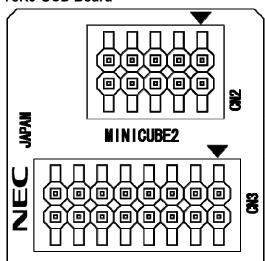

Figure 2-3. Part Names of 78K0-OCD Board

(1) CLK1

For clock supply to the target device, a 14-pin DIP socket is implemented as CLK1. A 14-pin type oscillator (5 V) or a parts board that can configure an oscillation circuit can be mounted on the 14-pin DIP socket. A parts board such as the 160-90-314 (manufactured by PRECI-DIP) can be used with this socket to configure oscillation circuit.

(2) CN1

This is a connector used to connect MINICUBE2 with the target interface connector of MINICUBE2. To prevent the 78K0-OCD board from being inserted by mistake, a dummy pin is mounted in the place of pin 11 in CN1. Pin 10 is not available.

(3) CN2

This is a connector used to connect MINICUBE2 with the target system, via a 10-pin target cable. A 10-core 2.54 mm pitch general-purpose connector (TSM-105-01-L-DV) is employed.

(4) CN3

This is a connector used to connect MINICUBE2 with the target system, via a 16-pin target cable. A 16-core 2.54 mm pitch general-purpose connector (TSM-108-01-L-DV) is employed.

CHAPTER 3 HOW TO USE MINICUBE2 WITH V850 SERIES

This chapter describes how to use MINICUBE2 when performing on-chip debugging and flash programming for a V850 Series microcontroller.

On-chip debugging is a method to debug a microcontroller mounted on the target system, using a debug function implemented in the device. Since debugging is performed with the target device operating on the board, this method is suitable for field debugging.

Flash programming is a method to write a program to the flash memory embedded in a device. Erasing, writing and verifying the program can be performed on-board with the device.

Read the following chapters if you are using MINICUBE2 for the first time with the V850 Series as the target device.

• 3.1 Target System Design

For communication between MINICUBE2 and the target system, communication circuits must be mounted on the target system. This section describes the circuit design and mounting of connectors.

3.2 On-Chip Debugging

This section describes the system configuration and startup method to perform on-chip debugging with MINICUBE2.

• 3.3 Flash Programming

This section describes the system configuration and startup method to perform flash programming with MINICUBE2.

3.1 Target System Design

This section describes the target system circuit design required for on-chip debugging and flash programming.

Figure 3-1 presents an overview of the MINICUBE2 communication interface. As shown on the left side of the figure, MINICUBE2 performs serial communication with the target device on the target system. For this communication, communication circuits must be mounted on the target system. Refer to this section to design circuits appropriately.

UART and CSI-H/S are supported as communication modes. Note that CSI-H/S is not available if there is no H/S pin connection. The H/S pin is the name of the pin for the programmer and this pin might not be described as an alternate-function pin in the user's manual of the device. In such a case, connect the relevant port that is assigned to the H/S pin. (In the V850ES/JJ, for example, the PCM0 pin is assigned to the H/S pin.)

The pins used for serial communication are basically the same as those of the flash memory programmer (such as PG-FP4), but some devices do not support some of them. Refer to the document "QB-MINI2 Operating Precautions" and check the supported pins.

Target device

Serial communication (UART, CSI-H/S)

Target system

Communication circuits must be mounted on the target system.

Figure 3-1. Outline of Communication Interface

3.1.1 Pin assignment

This section describes the interface signals used between MINICUBE2 and the target system. Table 3-1 lists the pin assignment. Table 3-2 describes the functions of each pin. The pin assignment varies depending on whether CSI-H/S or UART is used, so design the circuit appropriately according to the circuit connection examples described on the following sections.

Table 3-1. Pin Assignment Pin Name^{Note} Pin No. CSI-H/S Used **UART Used GND** 2 RESET_OUT 3 SI RXD 4 VDD 5 TXD SO 6 R.F.U. 7 SCK R.F.U. 8 H/S R.F.U. 9 CLK 10 R.F.U. 11 R.F.U. 12 FLMD1 R.F.U. 13 14 FLMD0 15 RESET_IN 16 R.F.U.

16 14 12 10 8 6 4 2

to be mounted on target system

Note Signal names in MINICUBE2

Table 3-2. Pin Functions

Pin Name	IN/OUT ^{Note}	Description
RESET_IN	IN	Pin used to input reset signal from the target system
RESET_OUT	OUT	Pin used to output reset signal to the target device
CLK	OUT	Pin used to output clock signal to the target device
FLMD0	OUT	Pin used to set the target device to debug mode or
		programming mode
FLMD1	OUT	Pin used to set programming mode
RxD/SI	IN	Pin used to receive command/data from the target device
TxD/SO	OUT	Pin used to transmit command/data to the target device
SCK	OUT	Pin used to output clock signal for 3-wire serial communication
H/S	IN	Pin used to input handshake signal from the target device
R.F.U.	_	This pin is not used, so leave it open.

Note As seen from MINICUBE2

3.1.2 Circuit connection examples

The circuit design on the target system varies depending on the communication interface mode. Refer to the following table and see the relevant circuit connection example.

Caution The constants described in the circuit connection example are reference values. If you perform flash programming aiming at mass production, thoroughly evaluate whether the specifications of the target device are satisfied.

Table 3-3. Corresponding Circuit Connection Diagrams

Communication Interface Mode	Refer to:		
UART	Figure 3-2		
CSI-H/S	Figure 3-3		

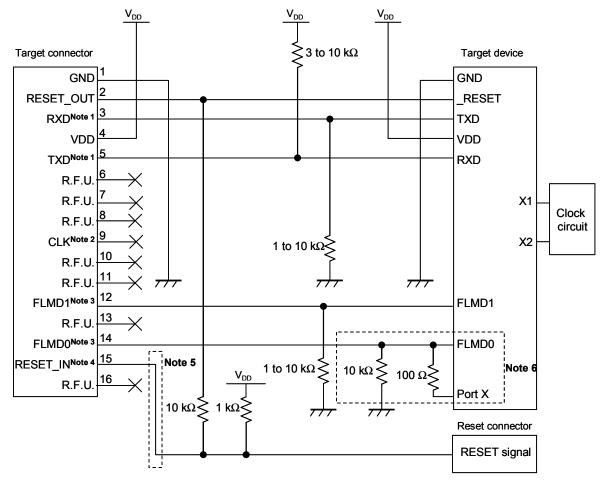

Figure 3-2. Recommended Circuit Connection When UART Is Used for Communication Interface

- **Notes 1.** Connect TxD (transmit side) of the target device to RxD (receive side) of the target connector, and TxD (transmit side) of the target connector to RxD (receive side) of the target device.
 - **2.** This pin may be used to supply an external clock during flash programming (4, 8 or 16 MHz). For the connection, refer to the user's manual for the target device.
 - **3.** The alternate function of this pin can be used because this pin goes to Hi-Z while the memory is not written during a break when debugging.
 - **4.** This connection is designed assuming that the RESET signal is output from the N-ch open-drain buffer (output resistance: 100Ω or less). For details, refer to **3.1.3 Connection of reset pin**.
 - 5. The circuit enclosed by a dashed line is not required when only flash programming is performed.
 - **6.** The circuit enclosed by a dashed line is designed for flash self-programming, which controls the FLMD0 pin via ports. Use the port for inputting or outputting the high level. When flash self-programming is not performed, a pull-down resistance for the FLMD0 pin can be within 1 to $10 \text{ k}\Omega$.

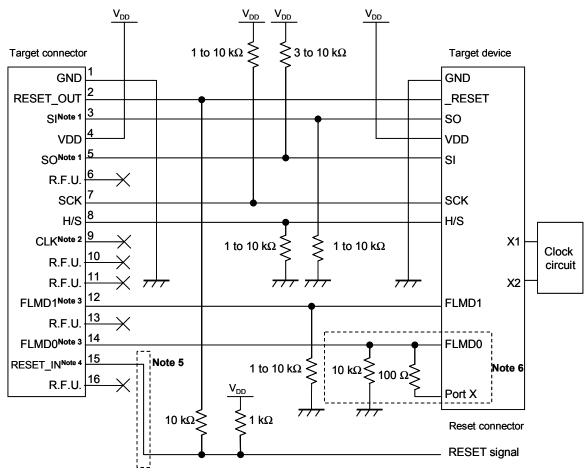

Figure 3-3. Recommended Circuit Connection When CSI-H/S Is Used for Communication Interface

- **Notes 1.** Connect SO (transmit side) of the target device to SI (receive side) of the target connector, and SO (transmit side) of the target connector to SI (receive side) of the target device.
 - **2.** This pin may be used to supply an external clock during flash programming (4, 8 or 16 MHz). For the connection, refer to the user's manual for the target device.
 - **3.** The alternate function of this pin can be used because this pin goes to Hi-Z while the memory is not written during a break when debugging.
 - **4.** This connection is designed assuming that the RESET signal is output from the N-ch open-drain buffer (output resistance: 100Ω or less). For details, refer to **3.1.3** Connection of reset pin.
 - 5. The circuit enclosed by a dashed line is not required when only flash programming is performed.
 - **6.** The circuit enclosed by a dashed line is designed for flash self-programming, which controls the FLMD0 pin via ports. Use the port for inputting or outputting the high level. When flash self-programming is not performed, a pull-down resistance for the FLMD0 pin can be within 1 to $10~\rm k\Omega$.

3.1.3 Connection of reset pin

This section describes the connection of the reset pin, for which special attention must be paid, in circuit connection examples shown in the previous section.

During on-chip debugging, a reset signal from the target system is input to MINICUBE2, masked, and then output to the target device. Therefore, the reset signal connection varies depending on whether MINICUBE2 is connected.

For flash programming, the circuit must be designed so that the reset signals of the target system and MINICUBE2 do not conflict.

Select one of the following methods and connect the reset signal in the circuit. The details of each method are described on the following pages.

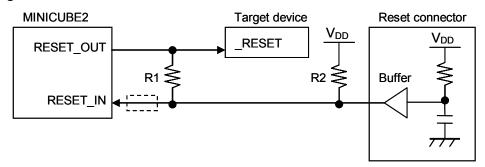

- (1) Automatically switching the reset signal via series resistor (recommended; described in recommended circuit connection in the previous section)
- (2) Manually switching the reset signal with jumper
- (3) Resetting the target device by power-on clear (POC) only

(1) Automatically switching the reset signal via series resistor

Figure 3-4 illustrates the reset pin connection described in **3.1.2** Circuit connection examples.

This connection is designed assuming that the reset circuit on the target system contains an N-ch open-drain buffer (output resistance: 100 Ω or less). The VDD or GND level may be unstable when the logic of RESET_IN/OUT of MINICUBE2 is inverted, so observe the conditions described below in **Remark**.

Figure 3-4. Circuit Connection with Reset Circuit That Contains Buffer

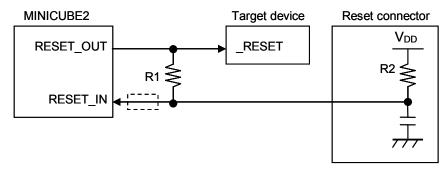

Remark Make the resistance of at least R1 ten times that of R2, R1 being 10 k Ω or more.

Pull-up resistor R2 is not required if the buffer of the reset circuit consists of CMOS output. The circuit enclosed by a dashed line is not required when only flash programming is performed.

Figure 3-5 illustrates the circuit connection for the case where the reset circuit on the target system contains no buffers and the reset signal is only generated via resistors or capacitors. Design the circuit, observing the conditions described below in **Remark**.

Figure 3-5. Circuit Connection with Reset Circuit That Contains No Buffers

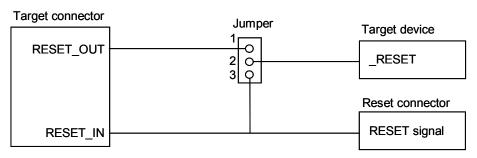

Remark Make the resistance of at least R1 ten times that of R2, R1 being 10 $k\Omega$ or more.

The circuit enclosed by a dashed line is not required when only flash programming is performed.

(2) Manually switching the reset signal with jumper

Figure 3-6 illustrates the circuit connection for the case where the reset signal is switched using the jumper, with or without MINICUBE2 connected. This connection is simple, but the jumper must be set manually.

Figure 3-6. Circuit Connection for Switching Reset Signal with Jumper

• Jumper setting

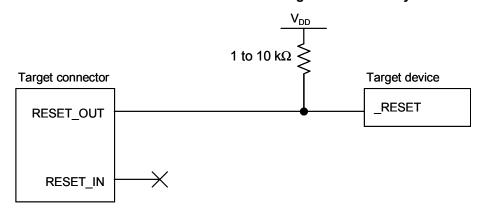

When MINICUBE2 is connected: 1-2 shorted When MINICUBE2 is not connected: 2-3 shorted

(3) Resetting the target device by power-on clear (POC) only

Figure 3-7 illustrates the circuit connection for the case where the target device is only reset via POC without using the reset pin. RESET_OUT is valid only when the debugger is running or during flash programming.

The operation is not guaranteed if the power to the target system is shut down during debugging. Note that the POC function cannot be emulated.

Figure 3-7. Circuit Connection for the Case Where Target Device Is Only Reset via POC

3.1.4 Mounting connector onto target system

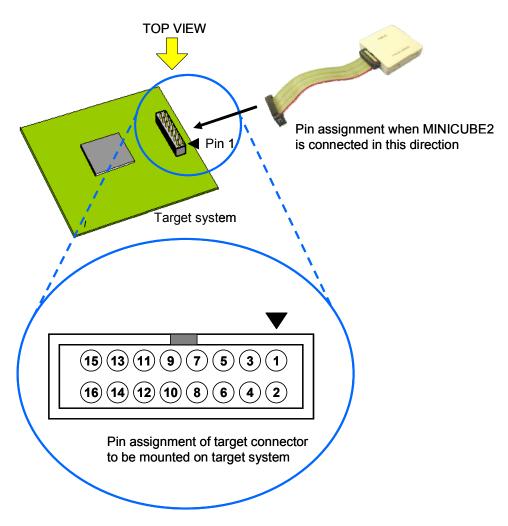

The connector must be mounted on the target system for connecting MINICUBE2 with the target system. A 2.54 mm pitch 16-pin general-purpose connector can be used. The following products are recommended.

- HIF3FC-16PA-2.54DS (right-angle type, made by Hirose Electric Co., Ltd.)
- HIF3FC-16PA-2.54DSA (straight type, made by Hirose Electric Co., Ltd.)
- 7616-5002PL (right-angle type, made by Sumitomo 3M, Ltd.)
- 7616-6002PL (straight type, made by Sumitomo 3M, Ltd.)

Compact connectors and loose-wire cables are also available as options. For more information on these products, access the MINICUBE2 information site.

URL: http://www.necel.com/micro/english/product/sc/allflash/minicube2.html

Figure 3-8. 2.54 mm Pitch 16-Pin General-Purpose Connector Pin Layout

3.2 On-Chip Debugging

This section describes the system configuration, startup/shutdown procedure and cautions for debugging when on-chip debugging is performed with MINICUBE2.

3.2.1 Debug functions

Table 3-4 lists the debug functions when the target device is the V850 Series and the ID850QB is used. If a debugger other than the ID850QB (made by partner manufacturer) is used, the available functions may differ, so check the specifications of the debugger used.

Functions Specifications Target interface UART or CSI-H/S 10-byte ID code authentication Security Download Available Go & Go, Start from Here, Come Here, Restart, step execution Execution 2 points Note 1 (commonly used by execution and access) Hardware break Software break ROM area 4 points 2,000 points RAM area Available Note 2 Forced break RAM monitoring Available DMM (writing to memory during RUN) Available Pin masking Available (reset pin only) Measurement resolution: 100 µs Time measurement (from execution start to break) Max. measurement time: Approximately 100 hours

Table 3-4. Debug Functions

Notes 1. The following devices are not yet supported.

User spaces used for debugging

V850ES/KE2, V850ES/KF2, V850ES/KG2, μ PD70F3733, V850ES/IE2

Internal RAM: 16 bytes max.

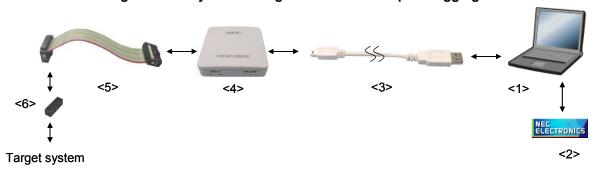

Internal ROM: 2 KB

2. Available with restrictions. For details, refer to 3.2.6 Cautions on debugging.

3.2.2 System configuration

Figure 3-9 illustrates the system configuration for on-chip debugging.

Figure 3-9. System Configuration for On-Chip Debugging

<1> Host machine

Products with USB ports

<2> Software

Includes the debugger, USB driver, device files, and so on.

Download these NEC Electronics software from the following website (ODS).

URL: http://www.necel.com/micro/ods/eng/index.html

- <3> USB cable (accessory)
- <4> MINICUBE2 (this product)
- <5> 16-pin target cable (accessory)
- <6> Target connector (sold separately)

3.2.3 System startup procedure

This section describes the system startup procedure. Observe the following order.

(1) Preparation and installation of software

The following software is required to perform on-chip debugging. For details on preparation and installation of software, refer to the setup manual supplied with MINICUBE2.

- Debugger
- USB driver
- Device file (may be unnecessary when using a partner manufacture's debugger)

(2) Switch setting

Set the mode select switch to "M2". Set the power select switch by referring to Table 3-5.

Caution Do not change the switch setting while the USB cable is connected.

Table 3-5. Setting of Power Select Switch

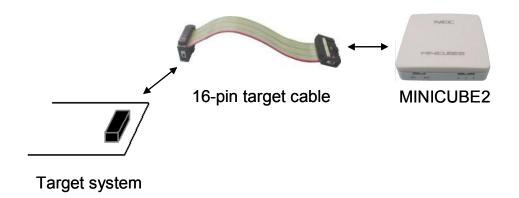

Setting	Description
3	3 V is supplied from MINICUBE2 to the target system (Factory setting)
5	5 V is supplied from MINICUBE2 to the target system Note.
Т	Power supply of the target system is used.
	MINICUBE2 detects the power for the target system.
	The detected power is also used as the power supply for the communication
	interface.

Note The maximum rating of the current is 100 mA, so do not use MINICUBE2 with the target system with the higher current rating. The power is always supplied after MINICUBE2 is connected to the host machine.

(3) Connecting the target system

Connect MINICUBE2 to the target system as shown in Figure 3-10, before the power to the target system is turned on.

Figure 3-10. Connecting MINICUBE2 to Target System

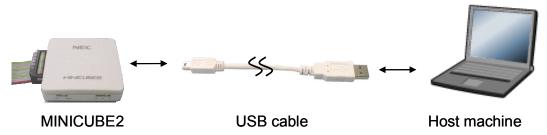

(4) Connecting the USB cable

Connect MINICUBE2 to the host machine as shown in Figure 3-11, before the power to the target system is turned on.

When the power select switch is set to "T", the mode LED flashes white after connection.

When the power select switch is set to "3" or "5", the mode LED glows white after connection.

Figure 3-11. Connecting MINICUBE2 to Host Machine

(5) Applying power to target system

Turn on power to the target system. This step is not necessary if the power select switch is set to "3" or "5". The mode LED glows white after power application.

(6) Debugger startup

Start the debugger. The mode LED glows blue after debugger startup.

For the operation after this step, refer to the user's manual for the debugger.

If the debugger does not start normally or the operation is unstable, the possible causes may be the following.

- Communication error between MINICUBE2 and target system
 Whether communication is performed normally can be checked using the OCD Checker. For details, refer to the user's manual for the OCD Checker.
- The user resource has not been secured or the security ID has not been set
 To perform debugging with MINICUBE2, the debug monitor area and communication serial interface for communication must be secured and the security ID must be set. For details, refer to 3.2.5 Securing of user resources and setting of security ID.
- Unsupported software (debugger, device file, or firmware) is used
 The software used may not support debugging of the target device. Refer to the document
 "QB-MINI2 Operating Precautions" and check the supported version. When using software provided by an NEC Electronics partner, refer to the documents prepared by the partner company.
- Defect of MINICUBE2
 MINICUBE2 may have a defect. Refer to CHAPTER 6 SELF-TESTING.

3.2.4 System shutdown procedure

Terminate debugging and shutdown the system in the following order.

If the following order is not observed, the target system or MINICUBE2 may be damaged.

(1) Debugger termination

Terminate the debugger.

(2) Target system power shutdown

Shutdown the power supplied to the target system. This step is not necessary if the power select switch is set to "3" or "5".

(3) Unplugging the USB cable

Unplug the USB cable from MINICUBE2 or the host machine.

(4) Unplugging the target cable

Unplug the target cable from MINICUBE2 or the target system.

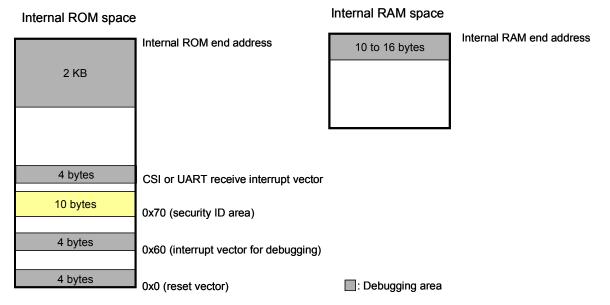

3.2.5 Securing of user resources and setting of security ID

The user must prepare the following to perform communication between MINICUBE2 and the target device and implement each debug function. Refer to the descriptions on the following pages and set these items in the user program or using the compiler options.

· Securement of memory space

The shaded portions in Figure 3-12 are the areas reserved for placing the debug monitor program, so user programs and data cannot be allocated in these spaces. These spaces must be secured so as not to be used by the user program.

Figure 3-12. Memory Spaces Where Monitor Programs for Debugging Are Allocated

Securement of serial interface for communication

The register settings, concerning UART or CSI-H/S used for communication between MINICUBE2 and the target device, performed by the debug monitor program must not be changed.

· Security ID setting

The ID code must be embedded in the area filled with yellow (0x70 to 0x79) in Figure 3-12, to prevent the memory from being read by an unauthorized person.

(a) Reset vector

A reset vector includes the jump instruction for the debug monitor program.

[How to secure areas]

It is not necessary to secure this area intentionally. When downloading a program, however, the debugger rewrites the reset vector in accordance with the following cases. If the rewritten pattern does not match the following cases, the debugger generates an error (F0c34 when using the ID850QB).

• When two nop instructions are placed in succession from address 0

Before writing After writing

0x0 nop Jumps to debug monitor program at 0x0

0x2 nop 0x4 xxxx

0x4 xxxx

When two 0xFFFF are successively placed from address 0 (already erased device)

Before writing After writing

0x0 0xFFFF Jumps to debug monitor program at 0x0

0x2 0xFFFF 0x4 xxxx

0x4 xxxx

The jr instruction is placed at address 0 (when using NEC Electronics compiler CA850)

Before writing After writing

0x0 jr disp22 Jumps to debug monitor program at 0x0

0x4 jr disp22 - 4

mov32 and jmp are placed in succession from address 0 (when using IAR compiler ICCV850)

Before writing After writing

Jumps to debug monitor program at 0x0 0x0 mov imm32,reg1 \rightarrow

0x4 mov imm32,reg1 0x6 jmp [reg1]

0xa jmp [reg1]

The jump instruction for the debug monitor program is placed at address 0

Before writing After writing

Jumps to debug monitor program at 0x0 No change

(b) Securement of area for debug monitor program

The shaded portions in Figure 3-12 are the areas where the debug monitor program is allocated. The monitor program performs initialization processing for debug communication interface and RUN or break processing for the CPU. The internal ROM area must be filled with 0xFF. This area must not be rewritten by the user program.

[How to secure areas]

It is not necessarily required to secure this area if the user program does not use this area.

To avoid problems that may occur during the debugger startup, however, it is recommended to secure this area in advance, using the compiler.

The following shows examples for securing the area, using the NEC Electronics compiler CA850. Add the assemble source file and link directive code, as shown below.

• Assemble source (Add the following code as an assemble source file.)

```
-- Secures 2 KB space for monitor ROM section
.section
            "MonitorROM", const
            0x800, 0xff
.space
-- Secures interrupt vector for debugging
            "DBG0"
.section
            4, 0xff
.space
-- Secures interrupt vector for serial communication
-- Change the section name according to serial communication mode used
.section
            "INTCSI00"
.space
            4, 0xff
-- Secures 16 byte space for monitor ROM section
            "MonitorRAM", bss
.section
.lcomm
                  monitorramsym, 16, 4
                                           /* defines monitorramsym symbol */
```

• Link directive (Add the following code to the link directive file.)

The following shows an example when the internal ROM end address is 0x3fffff and internal RAM end address is 0x3ffefff.

```
MROMSEG: !LOAD ?R V0x03f800{
    MonitorROM = $PROGBITS ?A MonitorROM;
};

MRAMSEG: !LOAD ?RW V0x03ffeff0{
    MonitorRAM = $NOBITS ?AW MonitorRAM;
};
```

(c) Securement of communication serial interface

UART or CSI-H/S is used for communication between MINICUBE2 and the target system. The settings related to the serial interface modes are performed by the debug monitor program, but if the setting is changed by the user program, a communication error may occur.

To prevent such a problem from occurring, communication serial interface must be secured in the user program.

[How to secure communication serial interface]
Create the user program observing the following points.

Serial interface registers

Do not set the registers related to UART and CSI-H/S in the user program.

Interrupt mask register

When UART is used, do not mask receive end interrupts^{Note}. When CSI-H/S is used, do not mask transmit end interrupts. The following shows an example.

Example Setting other than below is prohibited when the target device is the V850ES/KJ2 and CSI00 is used.

Note When the target device is the V850ES/IE2, do not mask receive error interrupts.

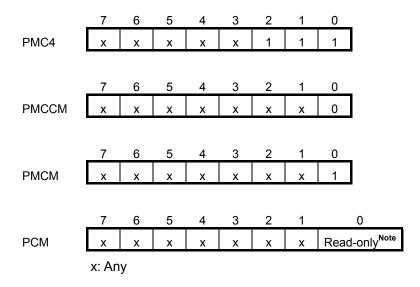

• Port registers

When UART is used, do not set port registers to make the TxD and RxD pins invalid. When CSI-H/S is used, do not set port registers to make the SI, SO, SCK and H/S pins invalid. The H/S pin is used as the port output for debugging. The following shows two examples.

Example 1 Setting other than below is prohibited when the target device is the V850ES/KJ2 and UART0 is used.

	7	6	5	4	3	2	1	0
PFC3	Х	Х	Х	Х	Х	Х	0	0
	7	6	5	4	3	2	1	0
PMC3L	х	Х	Х	Х	Х	Х	1	1
x: Any								

Example 2 Setting other than below is prohibited when the target device is the V850ES/HG2 and CSIB0 is used.

Note The port values corresponding to the H/S pin are changed by the monitor program according to the debugger status. To perform port register settings in 8-bit units, usually the user program can use read-modify-write. If an interrupt for debugging occurs before writing, however, an unexpected operation may be performed.

(d) Security ID setting

This setting is required to prevent the memory from being read by an unauthorized person. Embed a security ID at addresses 0x70 to 0x79 in the internal flash memory. The debugger starts only when the security ID that is set during debugger startup and the security ID set at addresses 0x70 to 0x79 match.

If bit 7 of address 0x79 is "0", however, debugging is disabled. In such a case, there are no methods to start the debugger. Debugging is mainly disabled for mass-produced devices.

If the user has forgotten the security ID or to enable debugging, erase the flash memory and set the security ID again.

[How to set security ID]

Embed a security ID at addresses 0x70 to 0x79 in the user program.

If the security ID is embedded as follows, for example, the security ID set by the debugger is "123456789ABCDEF123D4" (not case-sensitive).

Address	Value [7:0]
0x70	0x12
0x71	0x34
0x72	0x56
0x73	0x78
0x74	0x9A
0x75	0xBC
0x76	0xDE
0x77	0xF1
0x78	0x23
0x79	0xD4

If NEC Electronics compiler CA850 is used, the security ID can be set using the Compiler Common Options menu.

File | Startup | Link Directive | ROM | Flash | Device |

256M Byte Mode

BPC Register:

Security ID:

0x123456789ABCDEF123D4

This edit box can be specified a security ID by hexadecimal.
When it is specified, -Xsid option of the linker is set.

Figure 3-13. Security ID Setting with CA850

3.2.6 Cautions on debugging

This section describes cautions on on-chip debugging for the V850 Series.

Be sure to read the following to use MINICUBE2 properly.

(1) Handling of device that was used for debugging

Do not mount a device that was used for debugging on a mass-produced product, because the flash memory was rewritten during debugging and the number of rewrites of the flash memory cannot be guaranteed. Moreover, do not embed the debug monitor program into mass-produced products.

(2) When breaks cannot be executed

Forced breaks cannot be executed if one of the following conditions is satisfied.

- Interrupts are disabled (DI)
- Interrupts issued for the serial interface, which is used for communication between MINICUBE2 and the target device, are masked
- Standby mode is entered while standby release by a maskable interrupt is prohibited
- Mode for communication between MINICUBE2 and the target device is UART, and the main clock has been stopped

(3) When pseudo real-time RAM monitor (RRM) function and DMM function do not operate

The pseudo RRM function and DMM function do not operate if one of the following conditions is satisfied.

- Interrupts are disabled (DI)
- Interrupts issued for the serial interface, which is used for communication between MINICUBE2 and the target device, are masked
- · Standby mode is entered while standby release by a maskable interrupt is prohibited
- Mode for communication between MINICUBE2 and the target device is UART, and the main clock has been stopped
- Mode for communication between MINICUBE2 and the target device is UART, and a clock different from the one specified in the debugger is used for communication

(4) Standby release with pseudo RRM and DMM functions enabled

The standby mode is released by the pseudo RRM function and DMM function if one of the following conditions is satisfied.

- Mode for communication between MINICUBE2 and the target device is CSI-H/S
- Mode for communication between MINICUBE2 and the target device is UART, and the main clock has been supplied

(5) Writing to peripheral I/O registers that requires a specific sequence, using DMM function

Peripheral I/O registers that requires a specific sequence cannot be written with the DMM function.

(6) Device with which the debugger startup is slowed

When the debugger is started for the first time, chip erasure and writing of debug monitor program are performed. The following devices require about a dozen seconds for these operations.

V850ES/JG2, V850ES/JJ2

V850ES/HE2, V850ES/HF2, V850ES/HG2, V850ES/HJ2

V850ES/IE2

(7) Writing of debug monitor program

If the CPU operating clock setting is changed by the debugger, the debugger rewrites the debug monitor program. At this time, it takes about a dozen seconds for this operation. When using NEC Electronics debugger ID850QB, this specification applies when the setting in the Clock area in the Configuration dialog box.

(8) Flash self programming

If a space where the debug monitor program is allocated is rewritten by flash self programming, the debugger can no longer operate normally.

(9) Emulation of POC function

The POC function of the target device cannot be emulated. Make sure that the power to the target system is not shut down during debugging.

(10) Operation after reset

After an external pin reset or internal reset, the monitor program performs debug initialization processing. Consequently, the time from reset occurrence until user program execution differs from that in the actual device operation.

(11) Debugging with real machine running without using MINICUBE2

If debugging is performed with a real machine running, without using MINICUBE2, write the user program using the QB-Programmer. Programs downloaded by the debugger include the monitor program, and such a program malfunctions if it is not controlled via MINICUBE2.

3.3 Flash Programming

This section describes the system configuration and startup/shutdown procedure when flash programming is performed for the V850 Series using MINICUBE2.

3.3.1 Specifications of programming function

Table 3-6. Specifications of Programming Function

Functions	Specifications
Host interface	USB 2.0 (compatible with 1.1)
Target interface	UART or CSI-H/S
Target system voltage	2.7 to 5.5 V (depends on the target device)
Clock supply	16, 8, or 4 MHz clock can be supplied
	Clock mounted on the target system can be used
Power supply	3 or 5 V (maximum current rating: 100 mA)
Acquisition of device-specific	Parameter file for NEC Electronics PG-FP4 is used
information	
Security flag setting	Available
Standalone operation	Unavailable (must be connected to host machine)

3.3.2 System configuration

Figure 3-14 illustrates the system configuration for flash programming.

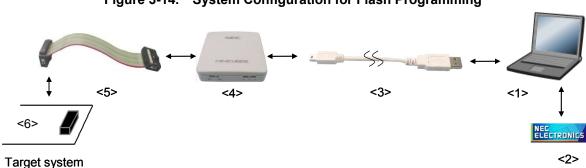

Figure 3-14. System Configuration for Flash Programming

<1> Host machine

Products with USB ports

<2> Software

Includes the QB-Programmer USB driver, parameter files, and so on.

Download these NEC Electronics software from the following website (ODS).

URL: http://www.necel.com/micro/ods/eng/index.html

- <3> USB cable (accessory)
- <4> MINICUBE2 (this product)
- <5> 16-pin target cable (accessory)
- <6> Target connector (sold separately)

3.3.3 System startup procedure

This section describes the system startup procedure. Observe the following order.

(1) Preparation and installation of software

The following software is required to perform flash programming. For details on preparation and installation of software, refer to the setup manual supplied with MINICUBE2.

- QB-Programmer
- USB driver
- Parameter file

(2) Switch setting

Set the mode select switch to "M2". Set the power select switch by referring to the following table.

Caution Do not change the switch setting while the USB cable is connected.

Table 3-7. Setting of Power Select Switch

Setting	Description	
3	3 V is supplied from MINICUBE2 to the target system Note.	
5	5 V is supplied from MINICUBE2 to the target system Note.	
Т	Power supply of the target system is used.	
	MINICUBE2 detects the power for the target system.	
	The detected power is also used as the power supply for the communication interface.	

Note The maximum rating of the current is 100 mA, so do not use MINICUBE2 with the target system with the higher current rating. The power is always supplied after MINICUBE2 is connected to the host machine.

(3) Connecting the target system

Connect MINICUBE2 to the target system as shown in Figure 3-15, **before the power to the target system is turned on**. When the power select switch is set to "T", the step of **(4) Connecting the USB cable** can be performed before this step.

Figure 3-15. Connecting MINICUBE2 to Target System

(4) Connecting the USB cable

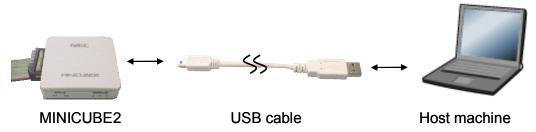

Connect MINICUBE2 to the host machine as shown in Figure 3-16, **before the power to the target system is turned on**.

When the power select switch is set to "T", the mode LED **flashes** white after connection.

When the power select switch is set to "3" or "5", the mode LED **glows** white after connection. The power is always supplied after MINICUBE2 is connected to the host machine with the USB cable.

Caution Do not change the switch setting while the USB cable is connected.

Figure 3-16. Connecting MINICUBE2 to Host Machine

(5) Applying power to target system

Turn on power to the target system. This step is not necessary if the power select switch is set to "3" or "5". The mode LED glows white after power application.

(6) QB-Programmer startup

Start the QB-Programmer from the Start menu of Windows. The mode LED glows green after QB-Programmer startup.

A series of basic operations after this step is described in the following section. For detailed usage of the QB-Programmer, refer to the **QB-Programmer User's Manual**.

3.3.4 Usage examples

This section describes a series of basic operations using the QB-Programmer, using the μ PD70F3732 as an example. The operations from execution of the [Autoprocedure (EPV)] command to programming for the target device are described. For other commands and their applications, refer to the QB-Programmer Programming GUI Operation User's Manual.

The conditions used for a series of operations in this section are as follows.

<Target system>

Target device: μ PD70F3732

Power supply voltage: 5 V (supplied from MINICUBE2)

Communication channel: CSI-H/S

<MINICUBE2>

Switches: Mode select switch: M2

Power select switch: 5

<QB-Programmer>

Parameter file: 70F3732.PRM

Clock setting: 5 MHz, x4 (oscillator on the target system side)

Operation mode: chip

Program file: sample.hex

Command options: [Blank check before Erase] selected

[Read verify after Program] selected

[Security flag after Program] selected

Security function: [Disable Read] selected

(1) Setting of programming environment

Set the programming environment, following the steps <1> to <7> described below.

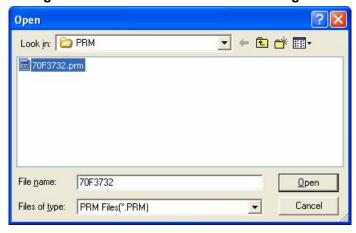

- <1> Click the [Device] menu on the menu bar and then click [Setup...].
- <2> The Device Setup dialog box appears, in which the [Standard] tab is active.

Figure 3-17. [Standard] Tab of Device Setup Dialog Box

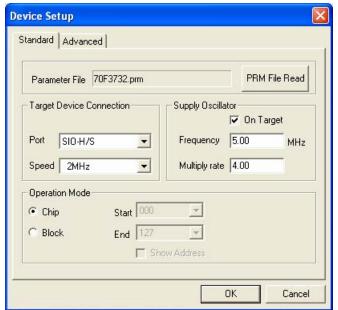

<3> Click the PRM File Read button to open the Parameter File Select dialog box. Select the parameter file for the target device and then click the Open button.

Figure 3-18. Parameter File Select Dialog Box

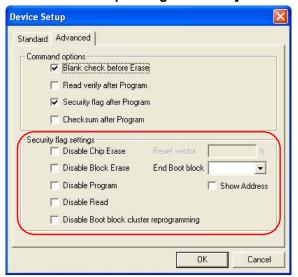

<4> Set the items in the [Target Device Connection], [Operation Mode] and [Supply Oscillator] areas, in accordance with your programming environment. The following figure shows an example.

Figure 3-19. [Standard] Tab of Device Setup Dialog Box After Setting

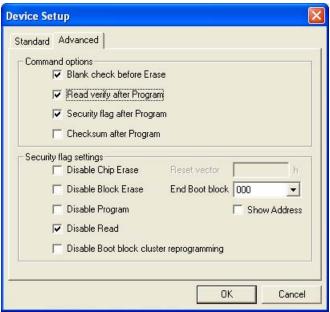

<5> The μPD70F3732 can use the [Get Security Settings] command, so click the OK button to return to the main window, click the [Device] menu and then click [Get Security Settings...]. After execution of this command, the security functions and boot area settings for the target device can be checked in the [Security flag settings] area on the [Advanced] tab in the Device Setup dialog box. For details, refer to the QB-Programmer Programming GUI Operation User's Manual.

Figure 3-20. [Advanced] Tab of Device Setup Dialog Box After [Get Security Settings...] Execution

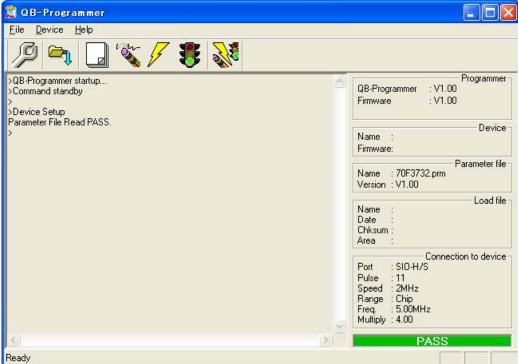

<6> Next, set the items in the [Command options] and [Security flag settings] areas, in accordance with your programming environment. The following figure shows an example.

<7> By clicking the OK button, the programming environment is set and the Device Setup dialog box is closed. The main window appears as follows.

Figure 3-22. Completion of Programming Environment Setting

(2) Selection of program file

Select the program file, following the steps <1> to <3> described below.

- <1> Click the [File] menu on the menu bar and then click [Load...].
- <2> The program file select dialog box appears.

<3> Select the program file for the target device and then click the Open button.

Figure 3-24. Completion of Program File Selection

(3) Execution of [Autoprocedure (EPV)] command

Click the [Device] menu on the menu bar and then click [Autoprocedure (EPV)].

The [Blank Check], [Erase] (if the flash memory in the target device is not blank), [Program], [Verify], and [Security] commands are executed for the target device sequentially. The mode LED on MINICUBE2 glows yellow during execution. When the command execution is completed normally, the mode LED glows green and the following window appears.

🚆 QB-Programmer Device Help 20% 30% 40% Programmer : V1.00 QB-Programmer Firmware : V1.00 50% 60% 70% 80% Device Name : UPD70FXXXXX Firmware: 2.00 90% 100% Parameter file PASS Verify Chip: 10% Name : 70F3732.prm Version: V1.00 Load file 20% 30% 40% : SAMPLE.HEX Name Date : 2006/02/24 21:13:08 Chksum: E23Eh 50% : 000000h-007FFFh Area 60% 70% 80% Connection to device : SIO-H/S Port 90% Pulse : 11 100% Speed 2MHz Range : Chip Freq. : 5.00MHz Multiply : 4.00 Set Security Flags AutoProcedure(Epv) PASS

Figure 3-25. Completion of [Autoprocedure (EPV)] Command Execution

3.3.5 System shutdown procedure

Terminate flash programming and shutdown the system in the following order.

If the following order is not observed, the target system or MINICUBE2 may be damaged.

(1) Terminating the QB-Programmer

Terminate the QB-Programmer if you are not going to perform programming to other devices.

Remark When the QB-Programmer is terminated, the setting information is saved in the *qbp.ini* file. Due to this file, the same setting is maintained when the QB-Programmer is started the next time.

(2) Target system power shutdown

Shutdown the power supplied to the target system. This step is not necessary if the power select switch is set to "3" or "5".

(3) Unplugging the USB cable

Unplug the USB cable from MINICUBE2 or the host machine.

When the power select switch is set to "T", the step of (4) Unplugging the target cable can be performed before this step.

(4) Unplugging the target cable

Unplug the target cable from MINICUBE2 or the target system.

3.3.6 Cautions on flash programming

This section describes the cautions for flash programming. Be sure to read the following for the proper use of MINICUBE2.

- To improve the writing quality, fully understand, verify, and evaluate the following items before using MINICUBE2.
 - Circuits are designed as described in the user's manuals for the device and MINICUBE2.
 - The device, QB-Programmer and MINICUBE2 are used as described in each user's manual.
 - The power supplied to the target system is stable.

CHAPTER 4 HOW TO USE MINICUBE2 WITH 78K0 SERIES

This chapter describes how to use MINICUBE2 when performing on-chip debugging and flash programming for a 78K0 Series microcontroller.

On-chip debugging is a method to debug a microcontroller mounted on the target system, using a debug function implemented in the device. Since debugging is performed with the target device operating on the board, this method is suitable for field debugging.

Flash programming is a method to write a program to the flash memory embedded in a device. Erasing, writing and verifying the program can be performed on-board with the device.

Read the following chapters if you are using MINICUBE2 for the first time with the 78K0 Series as the target device.

• 4.1 Target System Design

For communication between MINICUBE2 and the target system, communication circuits must be mounted on the target system. This section describes the circuit design and mounting of connectors.

• 4.2 On-Chip Debugging

This section describes the system configuration and startup method to perform on-chip debugging with MINICUBE2.

• 4.3 Flash Programming

This section describes the system configuration and startup method to perform flash programming with MINICUBE2.

4.1 Target System Design

This section describes the target system circuit design required for on-chip debugging and flash programming.

Figure 4-1 and Figure 4-2 present overviews of the MINICUBE2 communication interface. For communication between MINICUBE2 and the target system, communication circuits must be mounted on the target system, as shown on the left side of the figure. Refer to this section to design circuits appropriately.

Figure 4-1. Outline of Communication Interface for On-Chip Debugging

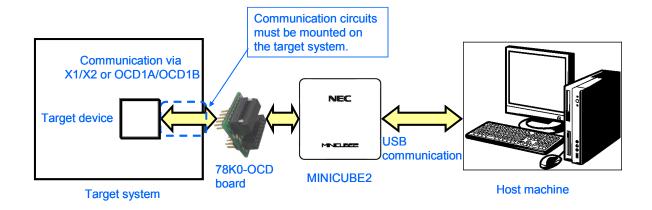

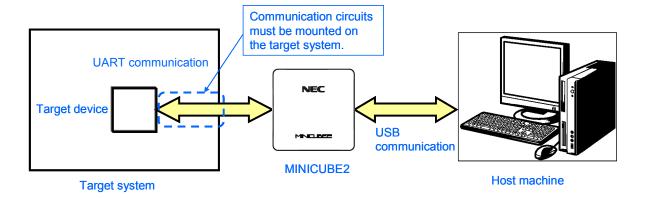

Figure 4-2. Outline of Communication Interface for Flash Programming

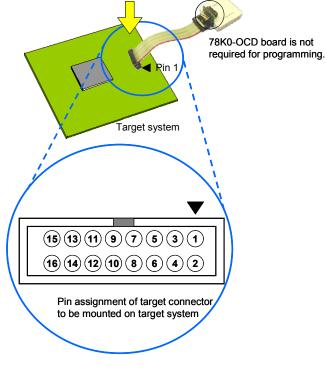

4.1.1 Pin assignment

This section describes the interface signals used between MINICUBE2 and the target system. Table 4-1 lists the pin assignment when a 16-pin target cable is used. Table 4-2 describes the functions of each pin. The pin assignment varies depending on whether the operation is debugging or programming, so design the circuit appropriately according to the circuit connection examples described on the following sections.

Table 4-1. Pin Assignment When Using 16-Pin Target Cable

4.1.2 Circuit connection examples

The circuit design on the target system varies depending on the used connector and interface signals. The following (1) to (3) are the major purpose of use. Confirm the purpose, refer to Table 4-5 and see

the relevant circuit connection example for specifications.

Caution The constants described in the circuit connection example are reference values. If you perform flash programming aiming at mass production, thoroughly evaluate whether the specifications of the target device are satisfied.

- (1) Used to perform on-chip debugging and flash programming via one 16-pin connector.
- (2) Used to perform on-chip debugging via a 10-pin connector.
 - * This type of circuit connection can be used with on-chip debugging emulator QB-78K0MINI.
- (3) Used to perform flash programming.

Table 4-5. Corresponding Circuit Connection Diagrams

Usage	Connector Used	Programming Interface	Debug Interface	Operating Clock Source Used by Target Device	Refer to:
(1)	16-pin connector	UART	X1, X2	Internal high-speed oscillator (X1 oscillator not used)	Figure 4-3
				X1 oscillator	Figure 4-4
			OCD1A, OCD1B	Internal high-speed oscillator (X1 oscillator not used)	Figure 4-5
				X1 oscillator	Figure 4-6

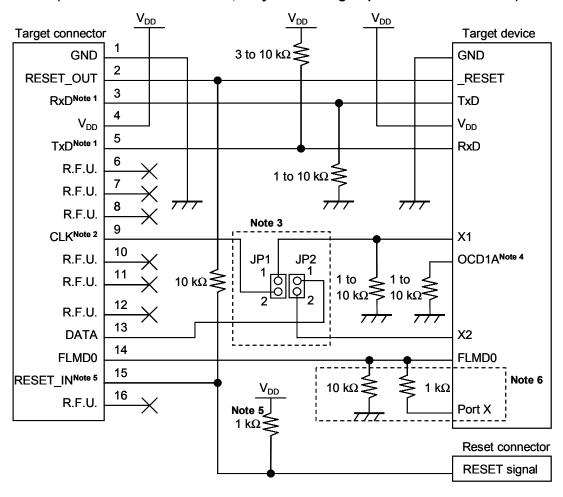

Figure 4-3. When Both Debugging and Programming Are Performed (with X1/X2 Communication, Only Internal High-Speed Oscillator Is Used)

- **Notes 1.** Connect TxD (transmit side) of the target device to RxD (receive side) of the target connector, and TxD (transmit side) of the target connector to RxD (receive side) of the target device.
 - **2.** During debugging, the clock mounted on the 78K0-OCD board can be supplied. If no clock is mounted, a clock of 4, 8, or 16 MHz can be supplied. During flash programming, only a clock of 4, 8, or 16 MHz can be supplied.
 - **3.** For debugging, short 1-2 of JP1 and 1-2 of JP2. For flash programming, short pin 2 of JP1 and JP2 only.
 - For the target device operation (without MINICUBE2 connected), leave JP1 and JP2 open.
 - **4.** OCD1A may be a different name, such as P31, depending on the device used. For details, refer to the user's manual for the target device.
 - 5. This connection is designed assuming that the RESET signal is output from the N-ch open-drain buffer (output resistance: 100 Ω or less). For details, refer to 4.1.3 Connection of reset pin.
 - **6.** The circuit enclosed by a dashed line is designed for flash self-programming, which controls the FLMD0 pin via ports. Use the port for inputting or outputting the high level. When flash self-programming is not performed, a pull-down resistance for the FLMD0 pin can be within 1 to $10~\rm k\Omega$.

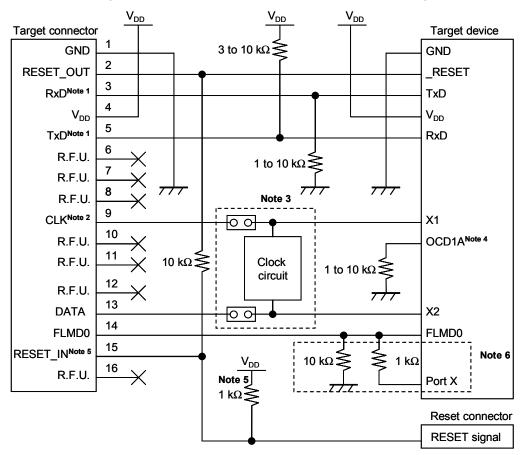

Figure 4-4. When Both Debugging and Programming Are Performed (with X1/X2 Communication, X1 Oscillator Is Used)

- **Notes 1.** Connect TxD (transmit side) of the target device to RxD (receive side) of the target connector, and TxD (transmit side) of the target connector to RxD (receive side) of the target device.
 - 2. During debugging, the clock mounted on the 78K0-OCD board can be supplied. If no clock is mounted, a clock of 4, 8, or 16 MHz can be supplied. During flash programming, use the clock mounted on the target system.
 - **3.** For debugging, short the jumper and mount no clock circuit. For flash programming, short pin 2 of JP1 and JP2 only.
 - For flash programming and the target device operation (without MINICUBE2 connected), leave the jumper open and mount a clock circuit.
 - **4.** OCD1A may be a different name, such as P31, depending on the device used. For details, refer to the user's manual for the target device.
 - 5. This connection is designed assuming that the RESET signal is output from the N-ch open-drain buffer (output resistance: 100Ω or less). For details, refer to 4.1.3 Connection of reset pin.
 - **6.** The circuit enclosed by a dashed line is designed for flash self-programming, which controls the FLMD0 pin via ports. Use the port for inputting or outputting the high level. When flash self-programming is not performed, a pull-down resistance for the FLMD0 pin can be within 1 to $10 \text{ k}\Omega$.

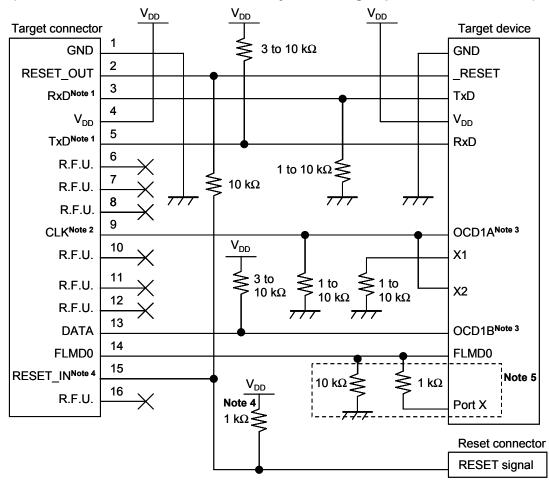

Figure 4-5. When Both Debugging and Programming Are Performed (with OCD1A/OCD1B Communication, Only Internal High-Speed Oscillator Is Used)

- **Notes 1.** Connect TxD (transmit side) of the target device to RxD (receive side) of the target connector, and TxD (transmit side) of the target connector to RxD (receive side) of the target device.
 - 2. During debugging, the clock mounted on the 78K0-OCD board can be supplied. If no clock is mounted, a clock of 4, 8, or 16 MHz can be supplied (neither of them is used for the CPU operating clock). During flash programming, only a clock of 4, 8, or 16 MHz can be supplied.
 - 3. OCD1A (OCD1B) may be a different name, such as P31, depending on the device used. Check the pin name with the user's manual for the target device. Since this pin is dedicated to debugging during debugging, port settings made by the user program are ignored. If this pin is assigned to an input port, the pin must be connected as shown in this figure, because it is open when MINICUBE2 is not connected.
 - **4.** This connection is designed assuming that the RESET signal is output from the N-ch open-drain buffer (output resistance: 100Ω or less). For details, refer to **4.1.3 Connection of reset pin**.
 - 5. The circuit enclosed by a dashed line is designed for flash self-programming, which controls the FLMD0 pin via ports. Use the port for inputting or outputting the high level. When flash self-programming is not performed, a pull-down resistance for the FLMD0 pin can be within 1 to $10~\rm k\Omega$.

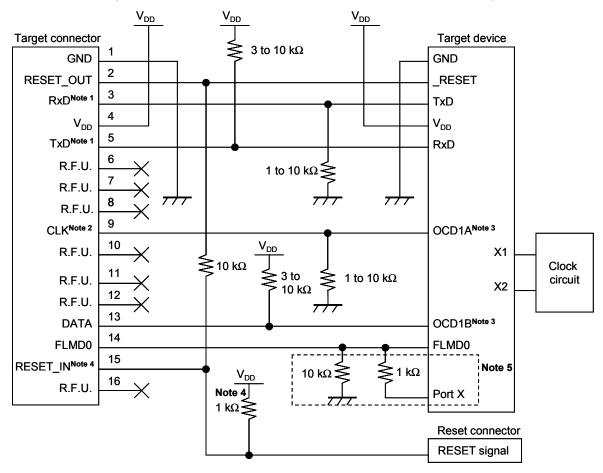

Figure 4-6. When Both Debugging and Programming Are Performed (with OCD1A/OCD1B Communication, X1 Oscillator Is Used)

- **Notes 1.** Connect TxD (transmit side) of the target device to RxD (receive side) of the target connector, and TxD (transmit side) of the target connector to RxD (receive side) of the target device.
 - 2. During debugging, the clock mounted on the 78K0-OCD board can be supplied. If no clock is mounted, a clock of 4, 8, or 16 MHz can be supplied (neither of them is used for the CPU operating clock). During flash programming, only a clock of 4, 8, or 16 MHz can be supplied.
 - 3. OCD1A (OCD1B) may be a different name, such as P31, depending on the device used. Check the pin name with the user's manual for the target device. Since this pin is dedicated to debugging during debugging, port settings made by the user program are ignored. If this pin is assigned to an input port, the pin must be connected as shown in this figure, because it is open when MINICUBE2 is not connected.
 - **4.** This connection is designed assuming that the RESET signal is output from the N-ch open-drain buffer (output resistance: 100Ω or less). For details, refer to **4.1.3 Connection of reset pin**.
 - 5. The circuit enclosed by a dashed line is designed for flash self-programming, which controls the FLMD0 pin via ports. Use the port for inputting or outputting the high level. When flash self-programming is not performed, a pull-down resistance for the FLMD0 pin can be within 1 to $10~\rm k\Omega$.

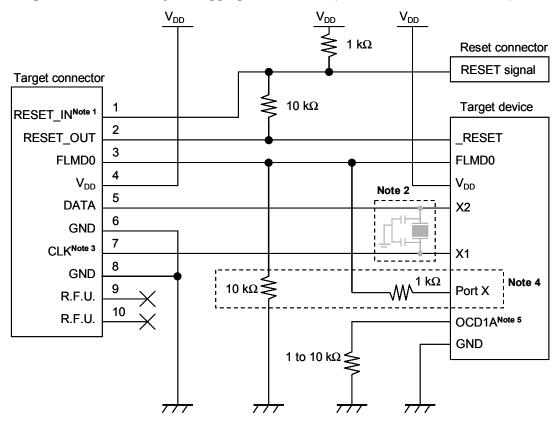

Figure 4-7. When Only Debugging Is Performed (with X1/X2 Communication)

- **Notes** 1. This connection is designed assuming that the RESET signal is output from the N-ch open-drain buffer (output resistance: 100Ω or less). For details, refer to 4.1.3 Connection of reset pin.
 - 2. For debugging, mount no clock circuit. For flash programming, mount a clock circuit.
 - **3.** During debugging, the clock mounted on the 78K0-OCD board can be supplied. If no clock is mounted, a clock of 4, 8, or 16 MHz can be supplied.
 - **4.** The circuit enclosed by a dashed line is designed for flash self-programming, which controls the FLMD0 pin via ports. Use the port for inputting or outputting the high level. When flash self-programming is not performed, a pull-down resistance for the FLMD0 pin can be within 1 to $10~\rm k\Omega$.
 - **5.** OCD1A may be a different name, such as P31, depending on the device used. For details, refer to the user's manual for the target device.

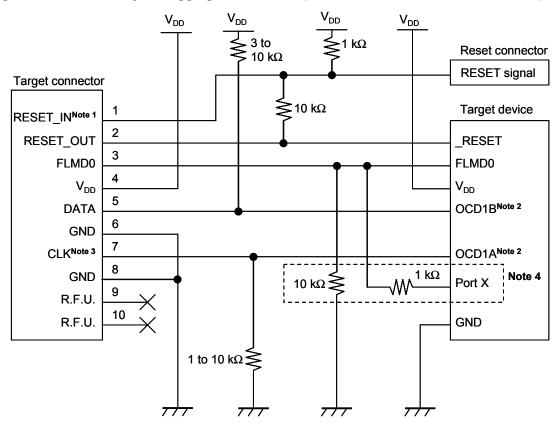

Figure 4-8. When Only Debugging Is Performed (with OCD1A/OCD1B Communication)

- **Notes 1.** This connection is designed assuming that the RESET signal is output from the N-ch open-drain buffer (output resistance: 100Ω or less). For details, refer to **4.1.3 Connection of reset pin**.
 - 2. OCD1A (OCD1B) may be a different name, such as P31, depending on the device used. Check the pin name with the user's manual for the target device. Since this pin is dedicated to debugging during debugging, port settings made by the user program are ignored. If this pin is assigned to an input port, the pin must be connected as shown in this figure, because it is open when MINICUBE2 is not connected.
 - **3.** During debugging, the clock mounted on the 78K0-OCD board can be supplied. If no clock is mounted, a clock of 4, 8, or 16 MHz can be supplied (neither of them is used for the CPU operating clock).
 - **4.** The circuit enclosed by a dashed line is designed for flash self-programming, which controls the FLMD0 pin via ports. Use the port for inputting or outputting the high level. When flash self-programming is not performed, a pull-down resistance for the FLMD0 pin can be within 1 to $10~\rm k\Omega$.

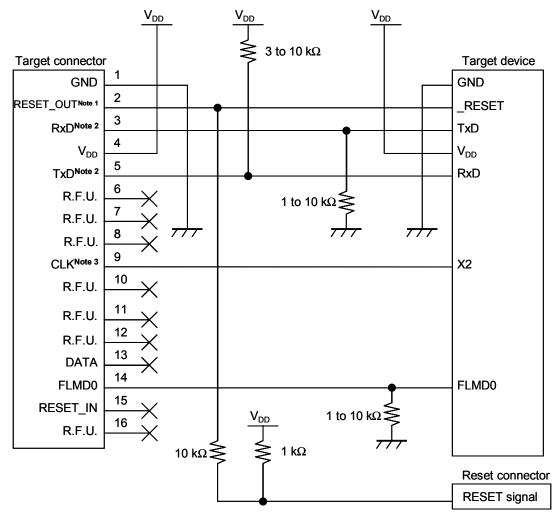

Figure 4-9. When Only Programming Is Performed

- **Notes** 1. This connection is designed assuming that the RESET signal is output from the N-ch open-drain buffer (output resistance: 100Ω or less). For details, refer to 4.1.3 Connection of reset pin.
 - 2. Connect TxD (transmit side) of the target device to RxD (receive side) of the target connector, and TxD (transmit side) of the target connector to RxD (receive side) of the target device.
 - **3.** This pin can be used to supply an external clock (4, 8 or 16 MHz). For the connection, refer to the user's manual for the target device. If this pin is not used, leave it open.

4.1.3 Connection of reset pin

This section describes the connection of the reset pin, for which special attention must be paid, in circuit connection examples shown in the previous section.

During on-chip debugging, a reset signal from the target system is input to MINICUBE2, masked, and then output to the target device. Therefore, the reset signal connection varies depending on whether MINICUBE2 is connected.

For flash programming, the circuit must be designed so that the reset signals of the target system and MINICUBE2 do not conflict.

Select one of the following methods and connect the reset signal in the circuit. The details of each method are described on the following pages.

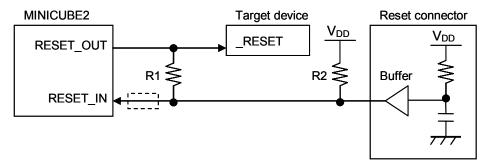

- (1) Automatically switching the reset signal via resistor (recommended; described in recommended circuit connection in the previous section)
- (2) Automatically switching the reset signal via selector logic
- (3) Manually switching the reset signal with jumper
- (4) Resetting the target device by power-on clear (POC) only

(1) Automatically switching the reset signal via resistor

Figure 4-10 illustrates the reset pin connection described in 4.1.2 Circuit connection examples.

This connection is designed assuming that the reset circuit on the target system contains an N-ch open-drain buffer (output resistance: 100 Ω or less). The VDD or GND level may be unstable when the logic of RESET_IN/OUT of MINICUBE2 is inverted, so observe the conditions described below in **Remark**.

Figure 4-10. Circuit Connection with Reset Circuit That Contains Buffer

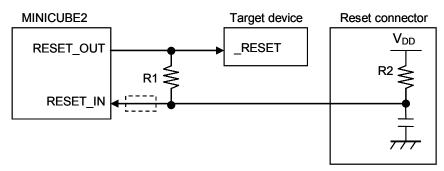

Remark Make the resistance of at least R1 ten times that of R2, R1 being 10 k Ω or more.

Pull-up resistor R2 is not required if the buffer of the reset circuit consists of CMOS output. The circuit enclosed by a dashed line is not required when only flash programming is performed.

Figure 4-11 illustrates the circuit connection for the case where the reset circuit on the target system contains no buffers and the reset signal is only generated via resistors or capacitors. Design the circuit, observing the conditions described below in **Remark**.

Figure 4-11. Circuit Connection with Reset Circuit That Contains No Buffers

Remark Make the resistance of at least R1 ten times that of R2, R1 being 10 k Ω or more.

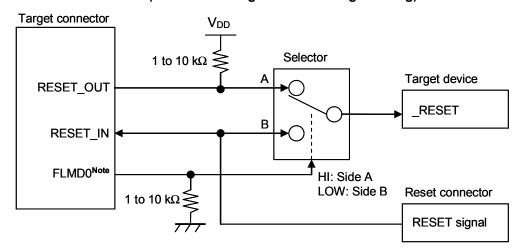

The circuit enclosed by a dashed line is not required when only flash programming is performed.

(2) Automatically switching the reset signal via selector logic

Figure 4-12 illustrates the circuit connection for the case where the reset signal is switched automatically using the selector logic, with or without MINICUBE2 connected. When using flash self programming, refer to Figure 4-13.

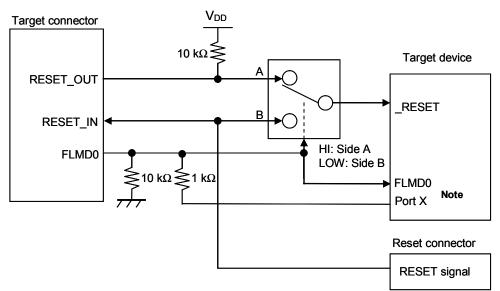

Caution The reset circuit is disconnected if flash self programming is performed (FLMD0 = HI) without MINICUBE2 connected, so no signals can be input to the _RESET pin.

Figure 4-12. Circuit Connection for Automatically Switching Reset Signal with Selector Logic (When Not Using Flash Self Programming)

Note FLMD0 is high level when MINICUBE2 is connected, and FLMD0 is pulled down when MINICUBE2 is not connected.

Figure 4-13. Circuit Connection for Automatically Switching Reset Signal with Selector Logic (When Using Flash Self Programming)

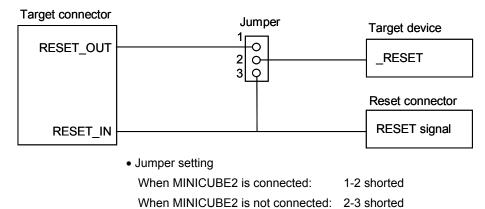

Note This circuit is designed for flash self-programming, which controls the FLMD0 pin via ports.

(3) Manually switching the reset signal with jumper

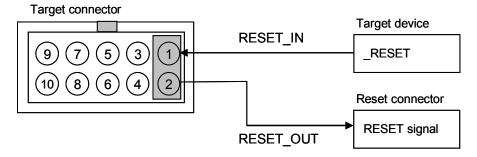

Figure 4-14 illustrates the circuit connection for the case where the reset signal is switched using the jumper, with or without MINICUBE2 connected. This connection is simple, but the jumper must be set manually.

Figure 4-14. Circuit Connection for Switching Reset Signal with Jumper

When a 10-pin connector is used, pins 1 and 2 of the target connector can also be used as the jumper, as shown in Figure 4-15.

Figure 4-15. Jumper Connection When 10-Pin Connector Is Used

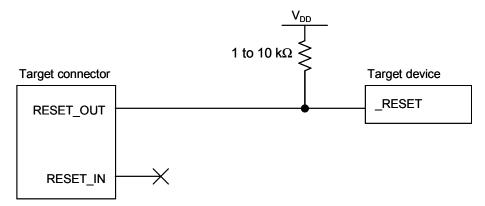

(4) Resetting the target device by power-on clear (POC) only

Figure 4-16 illustrates the circuit connection for the case where the target device is only reset via POC without using the reset pin. RESET_OUT is valid only when the debugger is running or during flash programming.

The operation is not guaranteed if the power to the target system is shut down during debugging. Note that the POC function cannot be emulated.

Figure 4-16. Circuit Connection for the Case Where Target Device Is Only Reset via POC

4.1.4 Cautions on target system design

Note the following cautions when designing the target system.

- Do not place X1/OCD1A and X2/OCD1B next to each other on the target system. If the layout requires this, they should be made as short as possible.
- Make the distance between the target connector and the target device as short as possible.
- Since the X1/OCD1A and X2/OCD1B lines are used for clock supply, be sure to shield them, such as with a GND pattern.
- Before shipping the product, use jumpers or other means to physically separate the X1/OCD1A and X2/OCD1B pins from the target connector in order to ensure normal clock oscillation.
- When debugging, remove capacitors, feedback resistors, and other elements for the resonator in order to prevent signal degradation due to the load placed on the X1/OCD1A and X2/OCD1B pins.

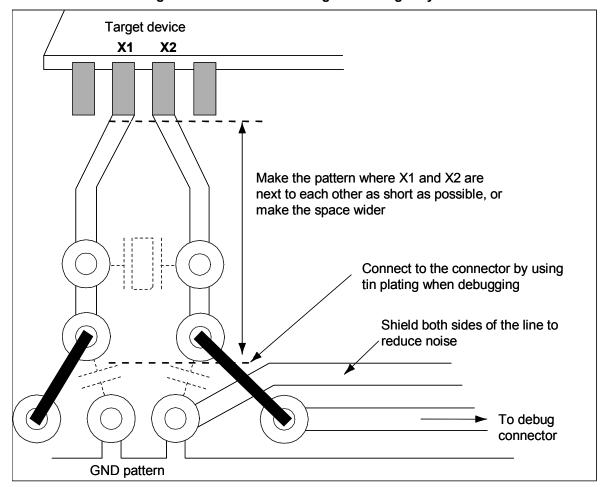

Figure 4-17. Reference Diagram of Target System

4.1.5 Mounting connector onto target system

The connector must be mounted on the target system for connecting MINICUBE2 with the target system. A 2.54 mm pitch 10- or 16-pin general-purpose connector can be used. The following products are recommended.

- HIF3FC-10PA-2.54DS (10-pin right-angle type, made by Hirose Electric Co., Ltd.)
- HIF3FC-10PA-2.54DSA (10-pin straight type, made by Hirose Electric Co., Ltd.)
- HIF3FC-16PA-2.54DS (16-pin right-angle type, made by Hirose Electric Co., Ltd.)
- HIF3FC-16PA-2.54DSA (16-pin straight type, made by Hirose Electric Co., Ltd.)
- 7616-5002PL (16-pin right-angle type, made by Sumitomo 3M, Ltd.)
- 7616-6002PL (16-pin straight type, made by Sumitomo 3M, Ltd.)

Compact connectors and loose-wire cables are also available as options. For more information on these products, access the MINICUBE2 information site.

URL: http://www.necel.com/micro/english/product/sc/allflash/minicube2.html

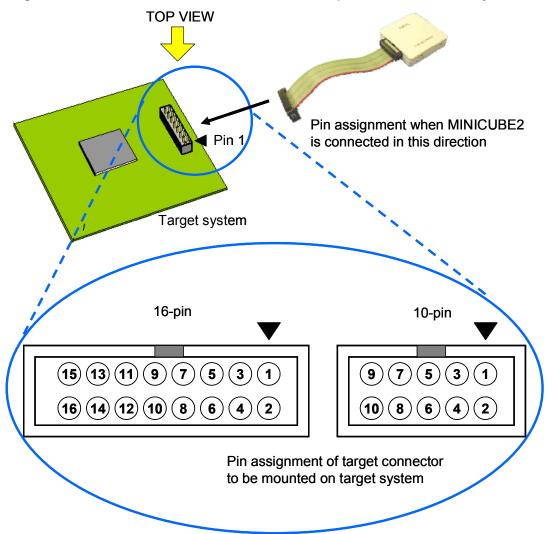

Figure 4-18. 2.54 mm Pitch 10-/16-Pin General-Purpose Connector Pin Layout

4.2 On-Chip Debugging

This section describes the system configuration, startup/shutdown procedure and cautions for debugging when on-chip debugging is performed with MINICUBE2.

4.2.1 Debug functions

Table 4-6 lists the debug functions when the target device is the 78K0 Series and the ID78K0-QB is used. If a debugger other than the ID78K0-QB (made by partner manufacturer) is used, the available functions may differ, so check the specifications of the debugger used

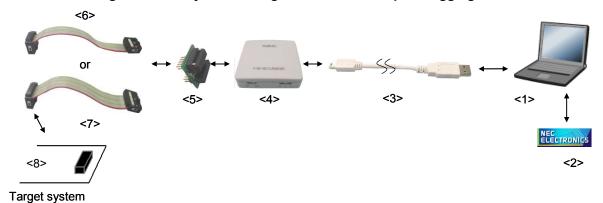

Table 4-6. Debug Functions

Functions	Specifications
Target interface	X1, X2 or OCD1A, OCD1B
Security	10-byte ID code authentication
Download	Available
Execution	Go & Go, Start from Here, Come Here, Restart, step execution
Hardware break	Break before execution: 1 point (unavailable when using software break)
	Access break: 1 point
Software break	2,000 points
Forced break	Available
Pseudo real-time RAM monitoring	Available
DMM (writing to memory during RUN)	Available
Pin masking	Available (reset pin only)
Time measurement	Resolution: 100 μ s
(from execution start to break)	Max. measurement time: Approximately 100 hours
User spaces used for debugging	Internal ROM: Min. 257 bytes (+ additional bytes when using RM function)
	Internal RAM: Min. 7 bytes

4.2.2 System configuration

Figure 4-19 illustrates the system configuration for on-chip debugging.

Figure 4-19. System Configuration for On-Chip Debugging

<1> Host machine

Products with USB ports

<2> Software

Includes the debugger, USB driver, device files, and so on.

Download these NEC Electronics software from the following website (ODS).

URL: http://www.necel.com/micro/ods/eng/index.html

- <3> USB cable (accessory)
- <4> MINICUBE2 (this product)
- <5> 78K0-OCD board (accessory)
- <6> 10-pin target cable (accessory)
- <7> 16-pin target cable (accessory)
- <8> Target connector (sold separately)

4.2.3 System startup procedure

This section describes the system startup procedure. Observe the following order.

(1) Preparation and installation of software

The following software is required to perform on-chip debugging. For details on preparation and installation of software, refer to the setup manual supplied with MINICUBE2.

- Debugger
- USB driver
- Device file (may be unnecessary when using a partner manufacture's debugger)

(2) Switch setting

Set the mode select switch to "M2". Set the power select switch by referring to Table 4-7.

Caution Do not change the switch setting while the USB cable is connected.

Setting

Description

3 3 V is supplied from MINICUBE2 to the target system Note.

5 5 V is supplied from MINICUBE2 to the target system Note.

T Power supply of the target system is used.

MINICUBE2 detects the power for the target system.

The detected power is also used as the power supply for the communication interface.

Table 4-7. Setting of Power Select Switch

Note The maximum rating of the current is 100 mA, so do not use MINICUBE2 with the target system with the higher current rating. The power is always supplied after MINICUBE2 is connected to the host machine.

(3) 78K0-OCD board setting

The settings of the 78K0-OCD board vary depending on how clock is supplied to the target device. A 20 MHz oscillator is mounted on the 78K0-OCD board at shipment. If either of the following conditions applies, the factory setting must be changed. Refer to **4.2.5 Clock setting** and set the clock.

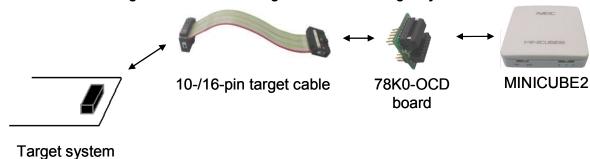

- The target device does not operate with a 20 MHz clock, or the target voltage that does not operate with 20 MHz clock is used
- A clock frequency other than 20 MHz is needed as the high-speed system clock.

(4) Connecting the target system

Connect MINICUBE2 to the target system as shown in Figure 4-20. Select a 10- or 16-pin target cable according to the target system circuit (refer to **Remark** below).

Perform connection before the power to the target system is turned on

Figure 4-20. Connecting MINICUBE2 to Target System

Remark Connect the 78K0-OCD board and the 10-/16-pin target cable as shown below. Do not connect both the 10-pin target cable and 16-pin target cable.

With 10-pin cable: Connect CN2 on the 78K0-OCD board to the 10-pin target cable (Figure 4-21).

With 16-pin cable: Connect CN3 on the 78K0-OCD board to the 16-pin target cable (Figure 4-22).

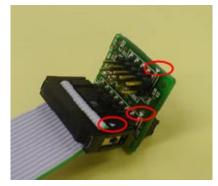

Figure 4-21. With 10-Pin Connector

Figure 4-22. With 16-Pin Connector

Caution Connect the 78K0-OCD board to the target cable so that pin 1 position (▲) on each side match.

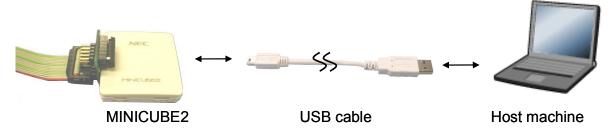

(5) Connecting the USB cable

Connect MINICUBE2 to the host machine as shown in Figure 4-23, **before the power to the target system is turned on**.

When the power select switch is set to "T", the mode LED flashes white after connection.

When the power select switch is set to "3" or "5", the mode LED glows white after connection.

Figure 4-23. Connecting MINICUBE2 to Host Machine

(6) Applying power to target system

Turn on power to the target system. This step is not necessary if the power select switch is set to "3" or "5". The mode LED glows white after connection after power application.

(7) Debugger startup

Start the debugger. The mode LED glows orange after debugger startup.

For the operation after this step, refer to the user's manual for the debugger.

If the debugger does not start normally or the operation is unstable, the possible causes may be the following.

- Communication error between MINICUBE2 and target system
 Whether communication is performed normally can be checked using the OCD Checker. For details, refer to the user's manual for the OCD Checker.
- The user resource has not been secured or the security ID has not been set
 To perform debugging with MINICUBE2, the user resource must be secured and the security ID must be set. For details, refer to 4.2.6 Securing of user resources and setting of security ID.
- Unsupported software (debugger, device file, or firmware) is used
 The software used may not support debugging of the target device. Refer to the document
 "QB-MINI2 Operating Precautions" and check the supported version. When using software provided by an NEC Electronics partner, refer to the documents prepared by the partner company.
- Defect of MINICUBE2
 MINICUBE2 may have a defect. Refer to CHAPTER 6 SELF-TESTING.

4.2.4 System shutdown procedure

Terminate debugging and shutdown the system in the following order.

If the following order is not observed, the target system or MINICUBE2 may be damaged.

(1) Debugger termination

Terminate the debugger.

(2) Target system power shutdown

Shutdown the power supplied to the target system. This step is not necessary if the power select switch is set to "3" or "5".

(3) Unplugging the USB cable

Unplug the USB cable from MINICUBE2 or the host machine.

(4) Unplugging the target cable

Unplug the target cable from MINICUBE2 or the target system.

4.2.5 Clock setting

MINICUBE2 can supply a clock to be used as the high-speed system clock. The setting of the 78K0-OCD board must be performed according to the following clock supply methods (1) to (3).

- (1) Using a clock mounted on the 78K0-OCD board
- (2) Using a clock (4, 8, or 16 MHz) generated in MINICUBE2
- (3) Using a clock mounted on the target system

The settings for (1) to (3) are described below.

Supplying a clock used as the subsystem clock is not supported.

(1) Using a clock mounted on the 78K0-OCD board

A clock generated by the oscillator mounted in CLK1 of the 78K0-OCD board or the oscillator clock can be supplied to the target device. The usable frequency is the same as that of the target device. Refer to (a) when using the oscillator, or (b) when mounting an oscillator.

(a) When using oscillator

Mount the 14-pin oscillator (5 V, CMOS type) in CLK1 of the 78K0-OCD board, as shown in Figure 4-24.

N.C. 1 14-pin type

14-pin type

14-pin type

1 14
2 13
3 12
4 11
5 10
6 9
7 8 Clock
7 8

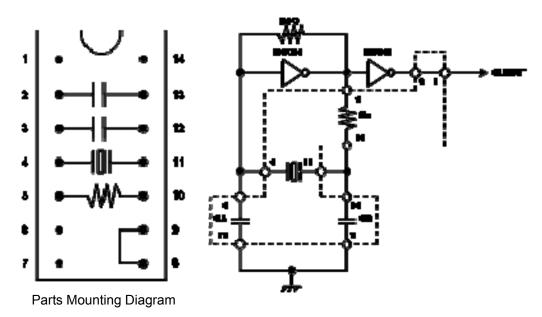

Figure 4-24. Mounting Oscillator

(b) When mounting an oscillator by using resonator

Refer to Figure 4-25 and mount an oscillator in CLK1 of the 78K0-OCD board. Figure 4-25 shows the appearance after mounting the oscillator.

"160-90-314" (made by PRECI-DIP) can be used as the parts board to be mounted in the socket.

Figure 4-25. 78K0-OCD Board Mounting Diagram and CLK1 Equivalent Circuit

CLK1 Equivalent Circuit

Pin Number	Connection
2-13	Capacitor CB
3-12	Capacitor CA
4-11	Ceramic resonator or crystal resonator
5-10	Resistance Rx
8-9	Shorted

Figure 4-26. Appearance After Mounting Oscillator

(2) Using a clock (4, 8, or 16 MHz) generated in MINICUBE2

Remove the oscillator or oscillation circuit on the 78K0-OCD board. The frequency of the supplied clock can be set in the debugger. For the settings, refer to the user's manual for the debugger.

When using the ID78K0-QB, this setting can be made in the Main Clock area in the Configuration dialog box (see below).

(3) Using a clock mounted on the target system

Remove the oscillator or oscillation circuit on the 78K0-OCD board.

The clock on the target system can be used only when the OCD1A and OCD1B pins are used as the communication interface. When the X1 and X2 pins are used as the communication interface, no oscillation circuits can be connected to the X1 and X2 pins of the device.

4.2.6 Securing of user resources and setting of security ID

MINICUBE2 uses the user memory spaces (shaded portions in Figure 4-27) to implement communication with the target device, or each debug functions. The areas marked with a dot (•) are always used for debugging, and other areas are used for each debug function used. Refer to the descriptions of (a) to (f) on the following pages and secure these spaces in the user program or using the compiler options.

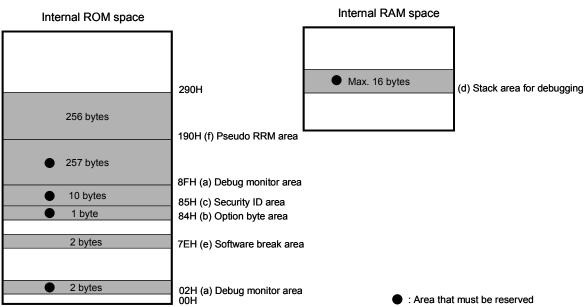

Figure 4-27. Reserved Area Used by MINICUBE2

(a) Debug monitor area (this area must be secured)

Addresses 0x02, 0x03 and area starting from address 0x8F must be secured to embed the debug monitor program.

If this area is rewritten by flash self programming, on-chip debugging can no longer be performed.

[How to secure areas]

When using NEC Electronics compiler CC78K0, addresses 0x02, 0x03 and area starting from address can be secured for debug monitoring, using the linker option (-go). Figure 4-28 shows the Linker Options dialog box of the project manager. Select the "On-Chip Debug" check box as shown in the figure below. If the pseudo RRM function is not used, set the size to 256 bytes (in actuality, 257 bytes from 0x8F to 0x18F are secured). If the pseudo RRM function is used, refer to (f).

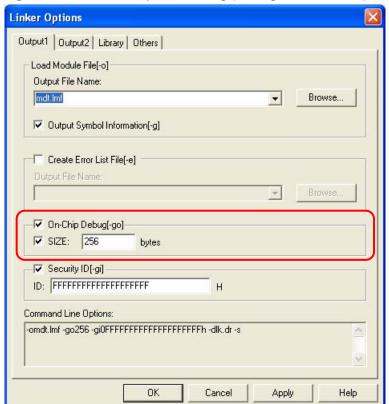

Figure 4-28. Linker Option Setting (Debug Monitor Area)

(b) Option byte area (essential)

This is the area for the security setting to prevent the flash memory from being read by an unauthorized person. The target device operates in accordance with the set value, as shown below.

Table 4-8. Option Byte Setting and Operation

Set Value	Description	Remark
0x00	Debugging is unavailable even if an on-chip debug This setting is availal	
	emulator (such as MINICUBE2) is connected.	only by flash programming.
0x02	The on-chip flash memory is not erased no matter	
	how many times the security ID code	
	authentication fails.	
0x03	All on-chip flash memory areas are erased if the	
	security ID code authentication fails.	
Other than above	Setting prohibited	

[How to set]

Describe the code for setting the option byte in the user program. Refer to the following and add a code to the assembler source.

Example When setting 0x02

SSS CSEG AT 084H; "SSS" is an arbitrary symbol name
DB 2H (eight characters or less)

Caution If address 0x84 is overwritten by 0x00 by self programming, communication is disabled, and debugging and connection can no longer be performed even if the debugger is restarted. In such as case, erase the memory via flash programming.

(c) Security ID area (essential)

This is the area for the security setting to prevent the flash memory from being read by an unauthorized person. The security ID functions as a password for starting the debugger. The debugger starts only when the security ID that is input during debugger startup and the security ID embedded in this area match.

[How to set]

When using NEC Electronics assembler RA78K0, an ID code is generated in this area, using the linker option (-gi). Figure 4-29 shows the Linker Options dialog box of the project manager. Select the "Security ID" check box as shown in the figure below and set an arbitrary ID code (10 bytes).

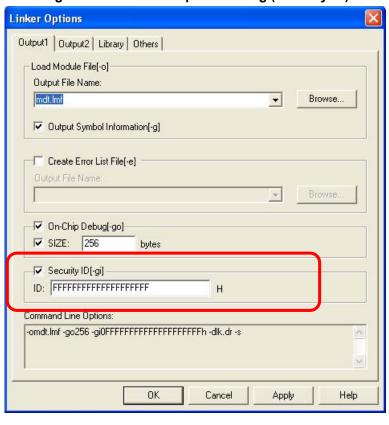

Figure 4-29. Linker Option Setting (Security ID)

(d) Stack area for debugging (this area must be secured)

This area requires 7 to 16 bytes as the stack area for debugging. Since this area is allocated immediately before the stack area, the address of this area varies depending on the stack increase and decrease.

Figure 4-30 illustrates the case where the stack area is increased when the internal high-speed RAM starts from 0xFB00, and the stack pointer initial value is 0xFEDF.

Figure 4-30. Variation of Address of Stack Area for Debugging <1> <2> <3> 0xFEDF 0xFEDF 0xFEDF Stack area Stack area for 7 bytes debugging 7 bytes Available space 0xFB07 in internal high-7 bytes 0xFB00 speed RAM 0xFB00 0xFB00

The size of this area also varies depending on whether software breaks or pseudo real-time RAM monitor is used.

Table 4-9. Size of Stack Area for Debugging

Item	Size of Stack Area for Debugging
Standard	7 bytes
When software breaks are used	9 bytes
When pseudo RRM is used	14 bytes
When software breaks and	16 bytes
pseudo RRM are used	

[How to secure areas]

Refer to the address range shown below and set the stack pointer.

Example When internal high-speed RAM starts from 0xFB00

- Standard

Within the range 0xFB07 to 0xFEDF

- When software breaks are used (also refer to (e))

Within the range 0xFB09 to 0xFEDF

- When pseudo real-time RAM monitor is used (also refer to (f))

0xFB0E to 0xFEDF

- When software breaks and pseudo real-time RAM monitor is used (also refer to **(e)** and **(f)**) 0xFB10 to 0xFEDF

(e) Software break area

This area is used for software breaks.

[How to secure areas]

Refer to the following and secure the area.

SSS CSEG AT 07EH; "SSS" is an arbitrary symbol name
DB 0FFH, 0FFH (eight characters or less)

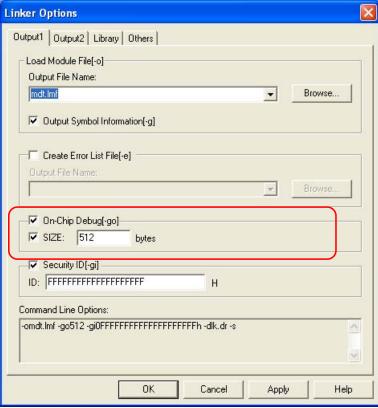

(f) Pseudo real-time RAM monitor (RRM) area

When pseudo real-time RAM monitor is used, the area of "debug monitor area specified in (a) + 256 bytes" must be reserved.

[How to secure areas]

When using NEC Electronics compiler CC78K0, the area used for pseudo real-time RAM monitoring can be secured using the linker option (-go). Figure 4-31 shows the Linker Options dialog box of the project manager. Add 256 bytes to the area specified in (a) (to make the area 512 bytes in total).

Figure 4-31. Linker Option Setting (When Pseudo RAM Monitor and Software Break Are Used)

4.2.7 Cautions on debugging

This section describes cautions on on-chip debugging for the 78K0 Series.

Be sure to read the following to use MINICUBE2 properly.

(1) Handling of device that was used for debugging

Do not mount a device that was used for debugging on a mass-produced product, because the flash memory was rewritten during debugging and the number of rewrites of the flash memory cannot be guaranteed.

(2) Overwriting flash memory during on-chip debugging

If the following operations are performed during on-chip debugging, the flash memory in the device is overwritten.

- <1> Downloading a program
- <2> Manipulation in Memory Fill dialog box
- <3> Manipulation in Memory Copy dialog box
- <4> Manipulation to change memory in Memory window
- <5> Online assembly in Assemble window
- <6> Settings when using software breaks
- <7> Program execution or software reset operation, while "Permit" has been selected for the Target Power Off setting in the Configuration dialog box
- <8> Operation that uses pseudo real-time RAM monitor function

It takes time from completion of flash memory programming until the control is passed to GUI.

(3) Software break (1)

During program running, do not rewrite the data at the address where a software break is set. This includes self programming and rewriting to RAM. If performed, the instruction placed at the address may be invalid.

(4) Boot swapping during self programming

The boot swapping function cannot be emulated. This is because boot swapping moves the memory spaces used for debugging, and thus the debug communication can no longer be performed.

(5) Emulation in self programming mode

For self programming, the mode is switched from normal mode to self programming mode.

MOV PFCMD,#0A5H MOV FLPMC,#1H \leftarrow (1) MOV FLPMC,#0FEH MOV FLPMC,#1H ----- From this position CALL !08100H ← (2) 1 MOV PFCMD,#0A5H MOV FLPMC,#0H Mode A1 MOV FLPMC,#0FFH MOV FLPMC,#0H \leftarrow (3) \downarrow ----- To this position

The section between (2) and (3) is in self programming mode A1. Step execution or debug operations, such as stopping program execution, cannot be performed in this section.

In addition, do not set a software break in the section between (1) and (3); otherwise the execution continues without a break but emulation is not performed normally.

(6) Break function for stack pointer initialization failure

This function executes a break when an interrupt occurs or a PUSH instruction is executed while the initial setting has not been made for the stack pointer.

If the manipulation or instruction shown below is executed immediately after a reset operation, the break function for stack pointer initialization failure becomes invalid.

- Setting a software break
- Write to the stack pointer from the Register window
- Write to the flash memory from the Memory window, etc

If a software break occurs while the initial setting has not been made for the stack pointer, the message "Uninitialized Stack Pointer" is displayed on the status bar.

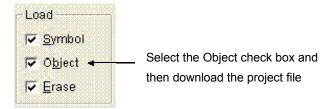

The subsequent operations are not performed normally, so make sure to set the SP value in the user program.

(7) Caution on downloading a HEX file

When downloading a HEX file, do not set specify a filling value other than 0xFF for the object converter option (-U).

(8) Software break (2)

If the debugger does not terminate normally due to a factor such as a freeze while a software break is set, the instruction for which the software break is set and that has been substituted by a debug instruction remains as is. To avoid this, select "Object" in the Download dialog box and download the load module. In particular, take care regarding this point when starting the debugger using a project file, as well as when using PM+.

(9) Caution on performing step execution

Some SFRs (special function registers) remain stopped during step execution. In such a case, execute the instruction with the real-time execution function.

(10) Cautions when using pseudo real-time RAM monitor function

- <1> The user program is stopped while the pseudo real-time RAM monitor function processing is being performed.
- <2> If the pseudo real-time RAM monitor function is executed during a standby state, the standby state is released.
- <3> The program temporarily operates with PCC = 0 during a break. This break time is extended when the system clock frequency is low or when the CPU operating speed is lowered.
- <4> When the pseudo real-time RAM monitor function processing is performed, the IXS value is forcibly set as shown below, so that the internal low-speed RAM area size becomes the maximum.

Device with OCD control code Note 1 V1.xx: 0Ah

Device with OCD control code V2.00 or later: 00h

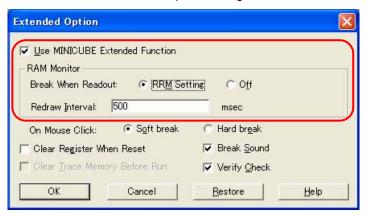

<5> If the interrupt disabled state (DI setting) is set or the operating clock is switched to internal oscillation clock^{Note 2} or subclock by the user program during the pseudo real-time RAM monitor function processing, the pseudo real-time RAM monitor function processing is suspended. A break occurs in the user program, for approximately 40 μs, due to the pseudo real-time RAM monitor function processing.

User program stop period: Approximately 40 μ s

- **Notes** 1. Version can be checked by selecting [About...] from the [Help] menu in the debugger.
 - 2. Devices with OCD control code V1.xx

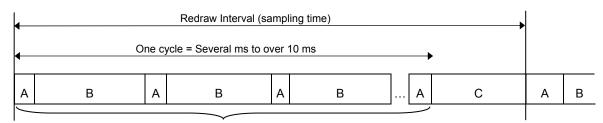

(11) Period in which user program is stopped while pseudo real-time RAM monitor function is being processed

The sampling time can be set in the Extended Option dialog box.

The following shows the execution time, whereas the operating frequency = 5 MHz and PCC = 0.

<When interrupts are enabled (EI) (with an RRM generated while a user program main routine is running)>

The A period occurs for the number of the RRM point bytes + 1.

RRM Function Sampling Range	Break Time per Cycle	Max. Interrupt Pending Time
2 bytes	$110 + 110 \times 2 = 330 \mu\text{s}$	110 <i>μ</i> s
4 bytes	$110 + 110 \times 4 = 440 \ \mu s$	110 <i>μ</i> s
16 bytes	110 + 110 × 16 = 1,870 μs	110 <i>μ</i> s

A (approx. 110 μs)
 : Pseudo real-time RAM monitor function processing in progress (during a break: RRM data collection and RRM data transmission)
 : User program is running.
 : User program is running (sampling time – A – (A + B) × sampling range).

(12) Caution on mounting a clock on 78K0-OCD board

When a clock is mounted on the 78K0-OCD board, power supply may not become the GND level even if the power to the target system is shut down.

(13) Emulation of POC function

The POC function of the target device cannot be emulated. Make sure that the power to the target system is not shut down during debugging

4.3 Flash Programming

This section describes the system configuration and startup/shutdown procedure when flash programming is performed for the 78K0 Series using MINICUBE2.

4.3.1 Specifications of programming function

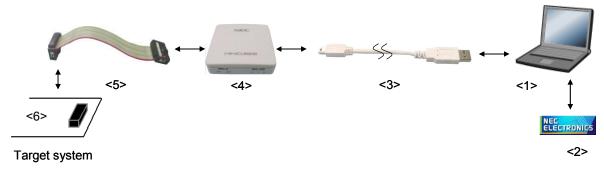

Table 4-10. Specifications of Programming Function

Functions	Specifications
Host interface	USB 2.0 (compatible with 1.1)
Target interface	UART
Target system voltage	2.7 to 5.5 V (depends on the target device)
Clock supply	16, 8, or 4 MHz clock can be supplied
	Clock mounted on the target system can be used
Power supply	3 or 5 V (maximum current rating: 100 mA)
Acquisition of device-specific	Parameter file for NEC Electronics PG-FP4 is used
information	
Security flag setting	Available
Standalone operation	Unavailable (must be connected to host machine)

4.3.2 System configuration

Figure 4-32 illustrates the system configuration for flash programming.

Figure 4-32. System Configuration for Flash Programming

<1> Host machine

Products with USB ports

<2> Software

Includes the QB-Programmer USB driver, parameter files, and so on.

Download these NEC Electronics software from the following website (ODS).

URL: http://www.necel.com/micro/ods/eng/index.html

- <3> USB cable (accessory)
- <4> MINICUBE2 (this product)
- <5> 16-pin target cable (accessory)
- <6> Target connector (sold separately)

4.3.3 System startup procedure

This section describes the system startup procedure. Observe the following order.

(1) Preparation and installation of software

The following software is required to perform flash programming. For details on preparation and installation of software, refer to the setup manual supplied with MINICUBE2.

- QB-Programmer
- USB driver
- Parameter file

(2) Switch setting

Set the mode select switch to "M2". Set the power select switch by referring to the following table.

Caution Do not change the switch setting while the USB cable is connected.

Table 4-11. Setting of Power Select Switch

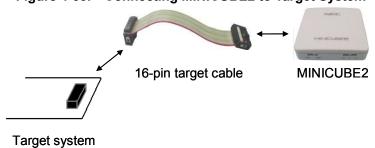

Setting	Description
3	3 V is supplied from MINICUBE2 to the target system Note.
5	5 V is supplied from MINICUBE2 to the target system Note.
Т	Power supply of the target system is used.
	MINICUBE2 detects the power for the target system.
	The detected power is also used as the power supply for the communication interface.

Note The maximum rating of the current is 100 mA, so do not use MINICUBE2 with the target system with the higher current rating. The power is always supplied after MINICUBE2 is connected to the host machine.

(3) Connecting the target system

Connect MINICUBE2 to the target system as shown in Figure 4-33, **before the power to the target system is turned on**. When the power select switch is set to "T", the step of **(4) Connecting the USB cable** can be performed before this step.

Figure 4-33. Connecting MINICUBE2 to Target System

(4) Connecting the USB cable

Connect MINICUBE2 to the host machine as shown in Figure 4-34, **before the power to the target system is turned on**.

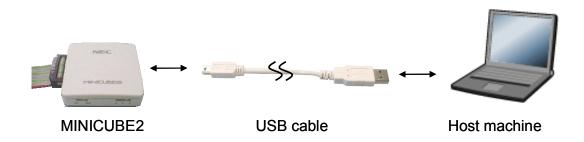

When the power select switch is set to "T", the mode LED **flashes** white after connection.

When the power select switch is set to "3" or "5", the mode LED glows white after connection.

The power is always supplied after MINICUBE2 is connected to the host machine with the USB cable.

Caution Do not change the switch setting while the USB cable is connected.

Figure 4-34. Connecting MINICUBE2 to Host Machine

(5) Applying power to target system

Turn on power to the target system. This step is not necessary if the power select switch is set to "3" or "5". The mode LED glows white after power application.

(6) QB-Programmer startup

Start the QB-Programmer from the Start menu of Windows. The mode LED glows green after QB-Programmer startup.

A series of basic operations after this step is described in the following section. For detailed usage of the QB-Programmer, refer to the QB-Programmer User's Manual.

4.3.4 Usage examples

This section describes a series of basic operations using the QB-Programmer, using the μ PD78F0547D as an example. The operations from execution of the [Autoprocedure (EPV)] command to programming for the target device are described. For other commands and their applications, refer to the QB-Programmer Programming GUI Operation User's Manual.

The conditions used for a series of operations in this section are as follows.

<Target system>

Target device: μ PD78F0547D

Power supply voltage: 5 V (supplied from MINICUBE2)

Communication channel: UART

<MINICUBE2>

Switches: Mode select switch: M2

Power select switch: 5

<QB-Programmer>

Parameter file: 78F0547D.PRM

Clock setting: 20 MHz, x1 (oscillator on the target system side)

Operation mode: chip

Program file: sample.hex

Command option: [Blank check before Erase] selected

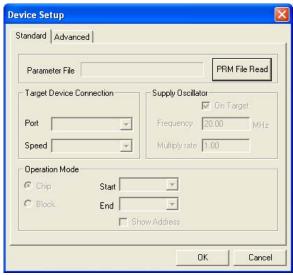

[Read Verify after Program] selected

(1) Setting of programming environment

Set the programming environment, following the steps <1> to <6> described below.

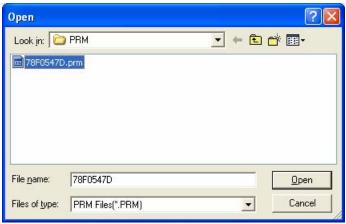

- <1> Click the [Device] menu on the menu bar and then click [Setup...].
- <2> The Device Setup dialog box appears, in which the [Standard] tab is active.

Figure 4-35. [Standard] Tab of Device Setup Dialog Box

<3> Click the PRM File Read button to open the Parameter File Select dialog box. Select the parameter file for the target device and then click the Open button.

Figure 4-36. Parameter File Select Dialog Box

<4> Set the items in the [Target Device Connection], [Operation Mode] and [Supply Oscillator] areas, in accordance with your programming environment. The following figure shows an example.

Figure 4-37. [Standard] Tab of Device Setup Dialog Box After Setting

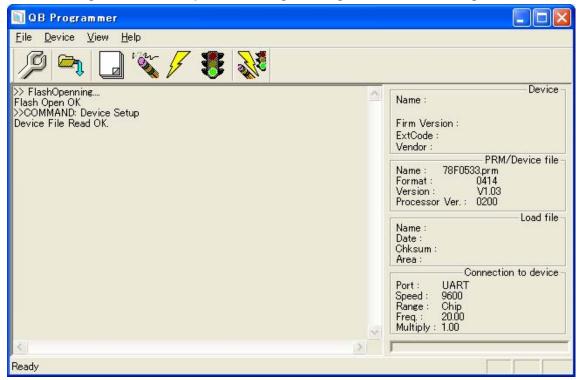

<5> Switch to the [Advanced] tab. Set the items in the [Command options] and [Security flag settings] areas, in accordance with your programming environment. The following figure shows an example.

Figure 4-38. [Advanced] Tab of Device Setup Dialog Box

<6> By clicking the OK button, the programming environment is set and the Device Setup dialog box is closed. The main window appears as follows.

Figure 4-39. Completion of Programming Environment Setting

(2) Selection of program file

Select the program file, following the steps <1> to <3> described below.

- <1> Click the [File] menu on the menu bar and then click [Load...].
- <2> The program file select dialog box appears.

<3> Select the program file for the target device and then click the Open button.

🚆 QB Programmer _ □ X <u>D</u>evice <u>V</u>iew <u>H</u>elp Device > FlashOpenning... >> riashOpen OK >>COMMAND: Device Setup Device File Read OK. >>COMMAND: Open Load File Success read HEX file. Name: Firm Version: ExtCode: Vendor: PRM/Device file 78F0533.prm 0414 V1.03 Name: Format: Version: Processor Ver.: 0200 Load file SAMPLE.HEX 2005/04/05 15:52:18 Name: Date: Chksum: E23Eh Area: 000000h-007FFFh Connection to device Port: UART Speed : Range : 115200 Range: Chip Freq.: 20.00 Multiply: 1.00 Ready

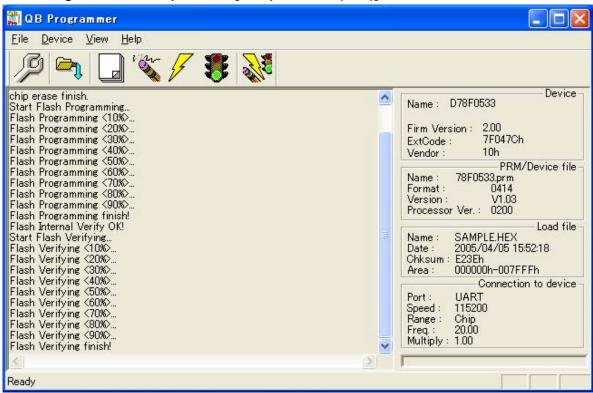

Figure 4-41. Completion of Program File Selection

(3) Execution of [Autoprocedure (EPV)] command

Click the [Device] menu on the menu bar and then click [Autoprocedure (EPV)].

The [Blank Check], [Erase] (if the flash memory in the target device is not blank), [Program], [Verify], and [Security] commands are executed for the target device sequentially. The mode LED on MINICUBE2 glows yellow during execution. When the command execution is completed normally, the mode LED glows green and the following window appears.

Figure 4-42. Completion of [Autoprocedure (EPV)] Command Execution

4.3.5 System shutdown procedure

Terminate flash programming and shutdown the system in the following order.

If the following order is not observed, the target system or MINICUBE2 may be damaged.

(1) Terminating the QB-Programmer

Terminate the QB-Programmer if you are not going to perform programming to other devices.

Remark When the QB-Programmer is terminated, the setting information is saved in the *qbp.ini* file. Due to this file, the same setting is maintained when the QB-Programmer is started the next time.

(2) Target system power shutdown

Shutdown the power supplied to the target system. This step is not necessary if the power select switch is set to "3" or "5".

(3) Unplugging the USB cable

Unplug the USB cable from MINICUBE2 or the host machine.

When the power select switch is set to "T", the step of (4) Unplugging the target cable can be performed before this step.

(4) Unplugging the target cable

Unplug the target cable from MINICUBE2 or the target system.

4.3.6 Cautions on flash programming

This section describes the cautions for flash programming. Be sure to read the following for the proper use of MINICUBE2.

- To improve the writing quality, fully understand, verify, and evaluate the following items before using MINICUBE2.
 - Circuits are designed as described in the user's manuals for the device and MINICUBE2.
 - The device, QB-Programmer and MINICUBE2 are used as described in each user's manual.
 - The power supplied to the target system is stable.

CHAPTER 5 HOW TO USE MINICUBE2 WITH 78K0S SERIES

This chapter describes how to use MINICUBE2 when performing on-chip debugging and flash programming for a 78K0S Series microcontroller.

To perform on-chip debugging for a 78K0S microcontroller, a specific program (debug function) must be downloaded to the device, and then debug the device mounted on the target system. Since debugging is performed with the target device operating on the board, this method is suitable for field debugging.

Flash programming is a method to write a program to the flash memory embedded in a device. Erasing, writing and verifying the program can be performed on-board with the device.

Read the following chapters if you are using MINICUBE2 for the first time with the 78K0S Series as the target device.

• 5.1 Target System Design

For communication between MINICUBE2 and the target system, communication circuits must be mounted on the target system. This section describes the circuit design and mounting of connectors.

• 5.2 On-Chip Debugging

This section describes the system configuration and startup method to perform on-chip debugging with MINICUBE2.

• 5.3 Flash Programming

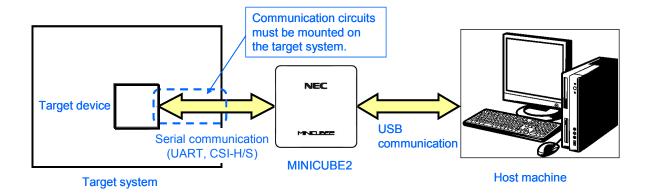

This section describes the system configuration and startup method to perform flash programming with MINICUBE2.

5.1 Target System Design

This section describes the target system circuit design required for on-chip debugging and flash programming.

Figure 5-1 presents an overview of the MINICUBE2 communication interface. As shown on the left side of the figure, MINICUBE2 performs serial communication with the target device on the target system. For this communication, communication circuits must be mounted on the target system. Refer to this section to design circuits appropriately.

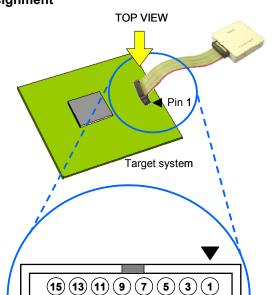

Figure 5-1. Outline of Communication Interface

5.1.1 Pin assignment

This section describes the interface signals used between MINICUBE2 and the target system. Table 5-1 lists the pin assignment. Table 5-2 describes the functions of each pin. The pin assignment varies depending on whether the operation is debugging or programming, so design the circuit appropriately according to the circuit connection examples described on the following sections.

Table 5-1. Pin Assignment Pin Name^{Note} Pin No. For Debugging For Programming **GND** 2 RESET_OUT 3 X2 4 **VDD** 5 X2 6 R.F.U. 7 R.F.U. 8 H/S 9 X1 10 R.F.U. 11 R.F.U. R.F.U. 12 INTP R.F.U. 13 14 X1 15 RESET_IN R.F.U. 16 R.F.U.

16 14 12 10 8 6 4 2

Pin assignment of target connector

to be mounted on target system

Note Signal names in MINICUBE2

Table 5-2. Pin Functions

1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1		
Pin Name	IN/OUT ^{Note}	Description
RESET_IN	IN	Pin used to input reset signal from the target system
RESET_OUT	OUT	Pin used to output reset signal to the target device
CLK	OUT	Pin used to output clock signal to the target device
X1	OUT	Pin used to output clock signal to the target device and
		to set the target device to programming mode
X2	IN/OUT	Pin used to receive commands or data from the target device
		and to transmit commands or data to the target device
H/S	IN	Pin used to input handshake signal from the target device
INTP	OUT	Pin used to set the target device to debug mode
R.F.U.	_	This pin is not used, so leave it open.

Note As seen from MINICUBE2

5.1.2 Circuit connection example

Refer to Figure 5-2 and design an appropriate circuit.

Caution The constants described in the circuit connection example are reference values. If you perform flash programming aiming at mass production, thoroughly evaluate whether the specifications of the target device are satisfied.

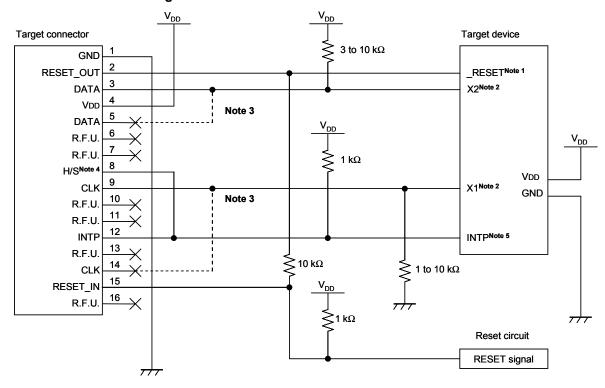

Figure 5-2. Recommended Circuit Connection

- **Notes 1.** The RESET pin is used to download the monitor program at debugger startup or to implement forced reset. Therefore, a pin that alternately functions as the RESET pin cannot be used. For reset pin connection, refer to **5.1.3 Connection of reset pin**.
 - 2. This is the pin connection when the X1 and X2 pins are not used in the target system. When using the X1 and X2 pins, refer to 5.1.5 Connection of X1 and X2 pins.
 - 3. No problem will occur if the dashed line portions are connected.
 - **4.** This pin is connected to enhance the accuracy of time measurement between run and break during debugging. Debugging is possible even if this pin is left open, but measurement error occurs in several ms units.
 - 5. The INTP pin is used for communication between MINICUBE2 and the target device during debugging. When debugging is performed with MINICUBE2, therefore, the INTP pin and its alternate-function pin cannot be used. For INTP pin connection, refer to 5.1.4 Connection of INTP pin.

5.1.3 Connection of reset pin

This section describes the connection of the reset pin, for which special attention must be paid, in the circuit connection example shown in the previous section.

During on-chip debugging, a reset signal from the target system is input to MINICUBE2, masked, and then output to the target device. Therefore, the reset signal connection varies depending on whether MINICUBE2 is connected.

For flash programming, the circuit must be designed so that the reset signals of the target system and MINICUBE2 do not conflict.

Select one of the following methods and connect the reset signal in the circuit. The details of each method are described on the following pages.

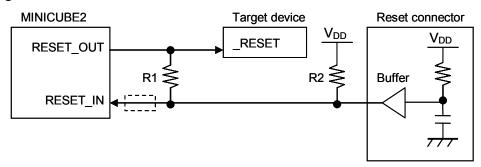

- (1) Automatically switching the reset signal via series resistor (recommended; described in recommended circuit connection in the previous section)
- (2) Manually switching the reset signal with jumper
- (3) Resetting the target device by power-on clear (POC) only

(1) Automatically switching the reset signal via series resistor

Figure 5-3 illustrates the reset pin connection described in **5.1.2** Circuit connection example.

This connection is designed assuming that the reset circuit on the target system contains an N-ch open-drain buffer (output resistance: 100 Ω or less). The VDD or GND level may be unstable when the logic of RESET_IN/OUT of MINICUBE2 is inverted, so observe the conditions described below in **Remark**.

Figure 5-3. Circuit Connection with Reset Circuit That Contains Buffer

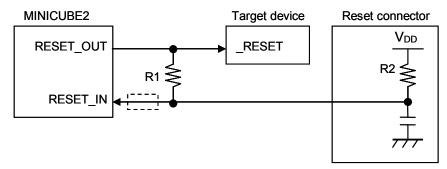

Remark Make the resistance of at least R1 ten times that of R2, R1 being 10 k Ω or more.

Pull-up resistor R2 is not required if the buffer of the reset circuit consists of CMOS output. The circuit enclosed by a dashed line is not required when only flash programming is performed.

Figure 5-4 illustrates the circuit connection for the case where the reset circuit on the target system contains no buffers and the reset signal is only generated via resistors or capacitors. Design the circuit, observing the conditions described below in **Remark**.

Figure 5-4. Circuit Connection with Reset Circuit That Contains No Buffers

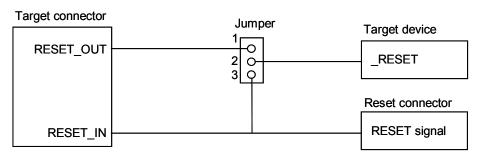

Remark Make the resistance of at least R1 ten times that of R2, R1 being 10 $k\Omega$ or more.

The circuit enclosed by a dashed line is not required when only flash programming is performed.

(2) Manually switching the reset signal with jumper

Figure 5-5 illustrates the circuit connection for the case where the reset signal is switched using the jumper, with or without MINICUBE2 connected. This connection is simple, but the jumper must be set manually.

Figure 5-5. Circuit Connection for Switching Reset Signal with Jumper

• Jumper setting

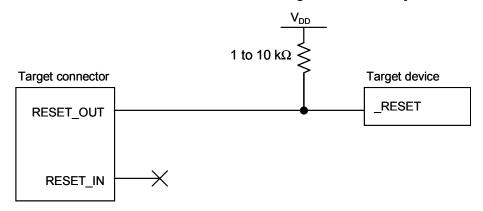

When MINICUBE2 is connected: 1-2 shorted When MINICUBE2 is not connected: 2-3 shorted

(3) Resetting the target device by power-on clear (POC) only

Figure 5-6 illustrates the circuit connection for the case where the target device is only reset via POC without using the reset pin. RESET_OUT is valid only when the debugger is running or during flash programming.

The operation is not guaranteed if the power to the target system is shut down during debugging. Note that the POC function cannot be emulated.

Figure 5-6. Circuit Connection for the Case Where Target Device Is Only Reset via POC

5.1.4 Connection of INTP pin

The INTP pin is used only for communication between MINICUBE2 and the target device during debugging. Design circuits appropriately according to the relevant case among the cases shown below.

- (1) INTP pin is not used in target system (as is illustrated in **Figure 5-2**. **Recommended Circuit Connection**)
 - \rightarrow See Figure 5-7.
- (2) MINICUBE2 is used only for programming, not for debugging
 - \rightarrow See Figure 5-8.
- (3) MINICUBE2 is used for debugging and debugging of the INTP pin is performed only with a real machine
 - \rightarrow See Figure 5-9.

Figure 5-7. Circuit Connection for the Case Where INTP Pin Is Not Used in Target System

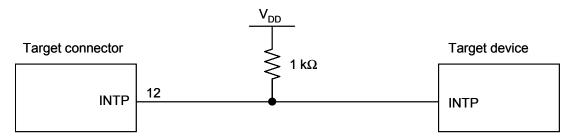

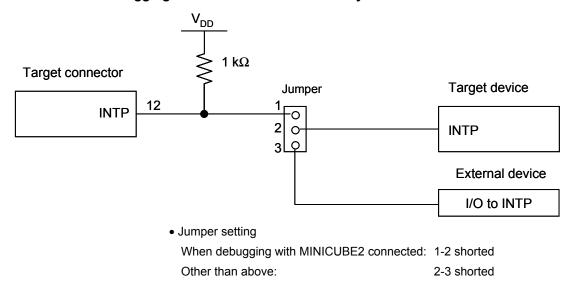

Figure 5-8. Circuit Connection for the Case Where MINICUBE2 Is Used Only for Programming

Figure 5-9. Circuit Connection for the Case Where MINICUBE2 Is Used for Debugging and Debugging of INTP Pin Is Performed Only with Real Machine

Caution If debugging is performed with a real machine running, without using MINICUBE2, write the user program using the QB-Programmer. Programs downloaded by the debugger include the monitor program, and such a program malfunctions if it is not controlled via MINICUBE2.

5.1.5 Connection of X1 and X2 pins

The X1 and X2 pins are used when the debugger is started for the first time (when downloading the monitor program) and when programming is performed with the QB-Programmer. Design circuits appropriately according to the relevant case among the cases shown below.

- (1) X1 and X2 pins are not used in target system
 - \rightarrow See Figure 5-10.
- (2) X1 and X2 pins are used in target system
 - → See Figure 5-11 and 5.2.6 Debugging of alternate-functions of X1 and X2 pins.

Figure 5-10. Circuit Connection for the Case Where X1 and X2 Pins Are Not Used in Target System

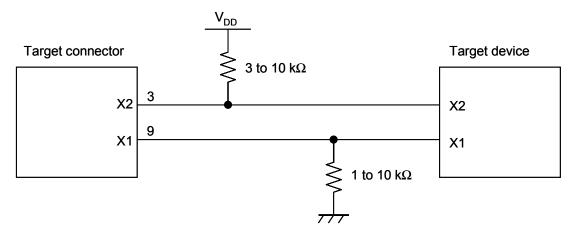

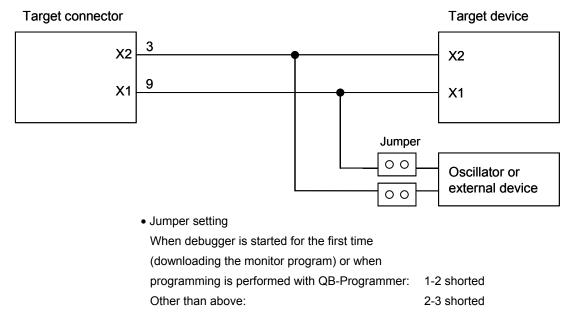

Figure 5-11. Circuit Connection for the Case Where X1 and X2 Pins Are Used in Target System

Remark Refer to the pin connection in Figure 5-10 when the X1 or X2 pin is not used.

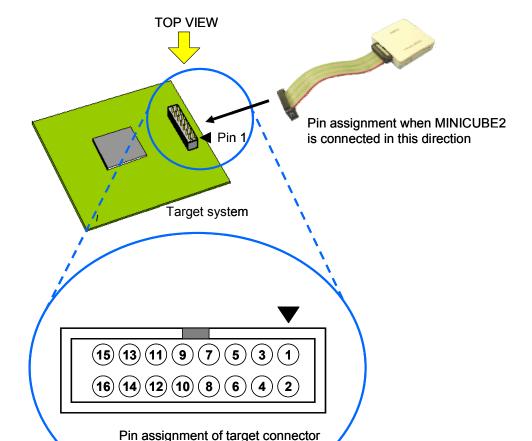

5.1.6 Mounting connector onto target system

The connector must be mounted on the target system for connecting MINICUBE2 with the target system. A 2.54 mm pitch 16-pin general-purpose connector can be used. The following products are recommended.

- HIF3FC-16PA-2.54DS (right-angle type, made by Hirose Electric Co., Ltd.)
- HIF3FC-16PA-2.54DSA (straight type, made by Hirose Electric Co., Ltd.)
- 7616-5002PL (right-angle type, made by Sumitomo 3M, Ltd.)
- 7616-6002PL (straight type, made by Sumitomo 3M, Ltd.)

Compact connectors and loose-wire cables are also available as options. For more information on these products, access the MINICUBE2 information site.

URL: http://www.necel.com/micro/english/product/sc/allflash/minicube2.html

to be mounted on target system

Figure 5-12. 2.54 mm Pitch 16-Pin General-Purpose Connector Pin Layout

5.2 On-Chip Debugging

This section describes the system configuration, startup/shutdown procedure and cautions for debugging when on-chip debugging is performed with MINICUBE2.

5.2.1 Debug functions

Table 5-3 lists the debug functions when the target device is the 78K0S Series and the ID78K0S-QB is used. If a debugger other than the ID78K0S-QB (made by partner manufacturer) is used, the available functions may differ, so check the specifications of the debugger used.

Table 5-3. Debug Functions

Functions	Specifications
Target interface	INTP, X1, X2 ^{Note}
Security ID	Unavailable
Download	Available
Execution	Go & Go, Start from Here, Come Here, Restart, step execution
Hardware break	Unavailable
Software break ROM	2,000 points
Forced break	Available except while interrupts are disabled
RAM monitoring	Unavailable
DMM (writing to memory during RUN)	Unavailable
Pin masking	Available (external reset pin only)
Time measurement	Measurement resolution: 100 μ s
(from execution start to break)	Max. measurement time: Approximately 100 hours
User spaces used for debugging	Internal ROM: Approximately 300 bytes
	Internal RAM: 5 bytes (used as stack)

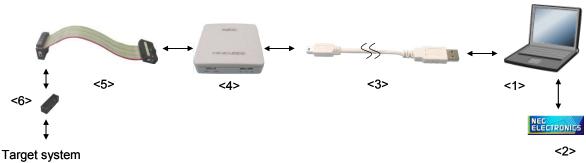

Note The INTP pins to be used are described in the document "QB-MINI2 Operating Precautions".

The X1 and X2 pins are used only when the debugger is started for the first time (when downloading the monitor program).

5.2.2 System configuration

Figure 5-13 illustrates the system configuration for on-chip debugging.

Figure 5-13. System Configuration for On-Chip Debugging

<1> Host machine

Products with USB ports

<2> Software

Includes the debugger, USB driver, device files, and so on.

Download these NEC Electronics software from the following website (ODS).

URL: http://www.necel.com/micro/ods/eng/index.html

- <3> USB cable (accessory)
- <4> MINICUBE2 (this product)
- <5> 16-pin target cable (accessory)
- <6> Target connector (sold separately)

5.2.3 System startup procedure

This section describes the system startup procedure. Observe the following order.

(1) Preparation and installation of software

The following software is required to perform on-chip debugging. For details on preparation and installation of software, refer to the setup manual supplied with MINICUBE2.

- Debugger
- USB driver
- Device file (may be unnecessary when using a partner manufacture's debugger)

(2) Switch setting

Set the mode select switch to "M1". Set the power select switch by referring to Table 5-4.

Caution Do not change the switch setting while the USB cable is connected.

Table 5-4. Setting of Power Select Switch

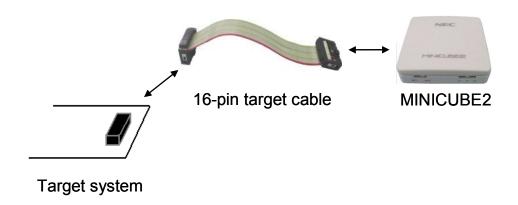

Setting	Description	
3	3 V is supplied from MINICUBE2 to the target system ^{Note} . (Factory setting)	
5	5 V is supplied from MINICUBE2 to the target system Note.	
Т	Power supply of the target system is used.	
	MINICUBE2 only detects the power for the target system.	

Note The maximum rating of the current is 100 mA, so do not use MINICUBE2 with the target system with the higher current rating. The power is always supplied after MINICUBE2 is connected to the host machine.

(3) Connecting the target system

Connect MINICUBE2 to the target system as shown in Figure 5-14, **before the power to the target system is turned on**.

Figure 5-14. Connecting MINICUBE2 to Target System

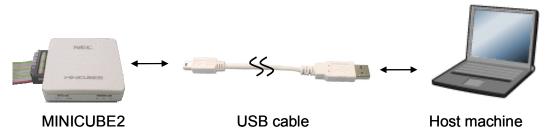

(4) Connecting the USB cable

Connect MINICUBE2 to the host machine as shown in Figure 5-15, before the power to the target system is turned on.

When the power select switch is set to "T", the mode LED flashes white after connection.

When the power select switch is set to "3" or "5", the mode LED **glows** white after connection.

Figure 5-15. Connecting MINICUBE2 to Host Machine

(5) Applying power to target system

Turn on power to the target system. This step is not necessary if the power select switch is set to "3" or "5". The mode LED glows white after power application.

(6) Debugger startup

Start the debugger. The mode LED glows green after debugger startup.

For the operation after this step, refer to the user's manual for the debugger.

If the debugger does not start normally or the operation is unstable, the possible causes may be the following.

- Communication error between MINICUBE2 and target system
 Whether communication is performed normally can be checked using the OCD Checker. For details, refer to the user's manual for the OCD Checker.
- The user resource has not been secured
 To perform debugging with MINICUBE2, the debug monitor area must be secured. For details,
 refer to 5.2.5 Securing of user resources.
- Unsupported software (debugger, device file, or firmware) is used
 The software used may not support debugging of the target device. Refer to the document
 "QB-MINI2 Operating Precautions" and check the supported version. When using software provided by an NEC Electronics partner, refer to the documents prepared by the partner company.
- Defect of MINICUBE2
 MINICUBE2 may have a defect. Refer to CHAPTER 6 SELF-TESTING.

5.2.4 System shutdown procedure

Terminate debugging and shutdown the system in the following order.

If the following order is not observed, the target system or MINICUBE2 may be damaged.

(1) Debugger termination

Terminate the debugger.

(2) Target system power shutdown

Shutdown the power supplied to the target system. This step is not necessary if the power select switch is set to "3" or "5".

(3) Unplugging the USB cable

Unplug the USB cable from MINICUBE2 or the host machine.

(4) Unplugging the target cable

Unplug the target cable from MINICUBE2 or the target system.

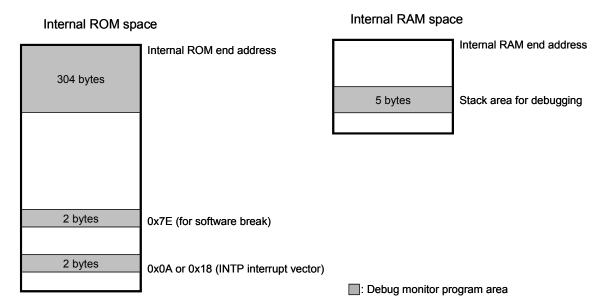

5.2.5 Securing of user resources

The user must prepare the following to perform communication between MINICUBE2 and the target device and implement each debug function. Refer to the descriptions on the following pages and set these items in the user program or using the compiler options.

Securement of memory space

The shaded portions in Figure 5-16 are the areas reserved for placing the debug monitor program, so user programs cannot be allocated in these spaces.

Figure 5-16. Memory Spaces Where Monitor Programs for Debugging Are Allocated

Securement of serial interface for communication
 The register settings, concerning the INTP pin used for communication between MINICUBE2 and

the target device, performed by the debug monitor program must not be changed.

(a) Securement of area for debug monitor program

In the internal ROM space of the target device, the shaded portions in Figure 5-16 are the areas where the debug monitor program is allocated. The monitor program performs initialization processing for debug communication interface and RUN or break processing for the CPU. The internal ROM area must be filled with 0xFF. This area must not be rewritten by the user program.

[How to secure areas]

It is not necessarily required to secure this area if the user program does not use this area.

To avoid problems that may occur during the debugger startup, however, it is recommended to secure this area in advance, using the compiler.

The following shows examples for securing the area, using the NEC Electronics assembler RA78K0S. Add the assemble source code, as shown below.

Assemble source example that securse INTP interrupt vector

```
SSS CSEG AT 0018h; "SSS" is an arbitrary symbol name (eight characters or less)

DB 0ffh, 0ffh
```

Remark Describe the INTP interrupt vector address to the portion of "0018h". The following shows examples of the 78K0S/Kx1+.

```
When using 78K0S/KU1+ or 78K0S/KY1+: INTP1 (0018h) When using 78K0S/KA1+ or 78K0S/KB1+: INTP3 (000ah)
```

Assemble source example that secures an area for software break

```
SSS CSEG AT 007eh; "SSS" is an arbitrary symbol name (eight characters or less)

DB 0ffh, 0ffh
```

 Assemble source example that secures monitor program area lower than internal ROM end address

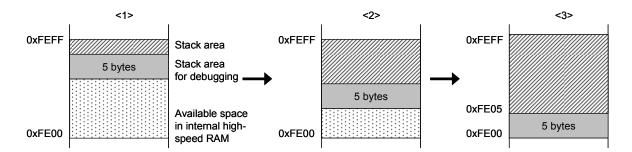

Remark Describe the address to the portion of "0ed0h" in accordance with the flash memory capacity of the target device (see the following table).

Flash Memory Capacity of	Value Described in
Target Device	Assembler Source
1 KB	0x2D0
2 KB	0x6D0
4 KB	0xED0
8 KB	0x1ED0

(b) Securement of stack area for debugging

In the internal RAM space of the target device, the shaded portion in Figure 5-16 are the area where the debug monitor program uses as the stack area (5 bytes). Since this area is allocated immediately before the stack area that is used by the user program, the address of this area varies depending on the stack increase and decrease. Therefore, the stack pointer must be set by making allowances for the stack size (5 bytes) used for debugging.

The following figure illustrates the case where the stack area is increased when the internal high-speed RAM starts from 0xFE00, and the stack pointer initial value is 0xFE00.

[How to secure areas]

Refer to the address range shown below and set the stack pointer.

Example When internal high-speed RAM starts from 0xFE00 Within the range 0xFE05 to 0xFEFA

(c) Securement of communication serial interface

The INTP pin is used for communication between MINICUBE2 and the target system. The settings related to the INTP pin are performed by the debug monitor program, but if the setting is changed by the user program, a communication error may occur.

To prevent such a problem from occurring, communication serial interface must be secured in the user program.

[How to secure communication serial interface]

Create the user program observing the following points.

· Interrupt mask flag register

Do not disable interrupts using the interrupt mask flag register corresponding to the INTP pin used.

Example Setting other than below is prohibited when the target device is the 78K0S/KB1+ and INTP3 is used.

• Port mode registers of alternate-function ports

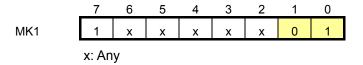

Do not set to the output mode the alternate-function port corresponding to the INTP pin used.

Example Setting other than below is prohibited when the target device is the 78K0S/KB1+ and INTP3 is used.

• External interrupt mode registers

Do not set to other than the rising edge the external interrupt mode register corresponding to the INTP pin used.

Example Setting other than below is prohibited when the target device is the 78K0S/KB1+ and INTP3 is used.

5.2.6 Debugging of alternate-functions of X1 and X2 pins

The X1 and X2 pins are used when the debugger is started for the first time (when downloading the monitor program) and when programming is performed with the QB-Programmer.

It is not necessary to use the X1 and X2 pins if the monitor program has already been downloaded to the target device, so the X1 and X2 pins and their alternate functions can be debugged by using the following procedures. To implement debugging of the X1 and X2 pins, the circuit must be designed appropriately. For details, refer to **5.1.5 Connection of X1 and X2 pins**.

- (1) Disconnect the external parts connected to the X1 and X2 pins in the target device. (If the circuit is designed as shown in Figure 5-11, short jumper pins 1 and 2.)
- (2) Turn on power to the target system and MINICUBE2 in accordance with **5.2.3 System startup** procedure.
- (3) Start the debugger. (The monitor program will be downloaded automatically immediately after startup.)
- (4) Terminate the debugger.
- (5) Turn off power to the target system and MINICUBE2 in accordance with **5.2.4 System shutdown** procedure.
- (6) Connect the external parts to the X1 and X2 pins in the target device. (If the circuit is designed as shown in Figure 5-11, short jumper pins 2 and 3.)
- (7) Turn on power to the target system and MINICUBE2 in accordance with **5.2.3 System startup procedure**.
- (8) Start the debugger.

Remark The next time the debugger is started, perform the procedure from step (7). However, if the program is written via the QB-Programmer and the monitor program is erased, the procedure must be performed from step (1) again.

5.2.7 Cautions on debugging

This section describes cautions on on-chip debugging for the 78K0S Series.

Be sure to read the following to use MINICUBE2 properly.

(1) Handling of device that was used for debugging

Do not mount a device that was used for debugging on a mass-produced product, because the flash memory was rewritten during debugging and the number of rewrites of the flash memory cannot be guaranteed.

(2) Cases where debugger operation speed is degraded

The debugger operation speed may be degraded when too many contents of the memory or registers are displayed in a debugger window, particularly when using a host machine with a USB 1.1 interface.

The debugger response is also slowed while the flash memory is being overwritten.

This phenomenon may be improved to some extent by raising the CPU operation clock frequency, by setting the PCC or PPCC register.

(3) Reset processing

If the RESET pin of the target device alternately functions as a port, enable the RESET pin by the user program settings, such as option byte setting.

(4) When breaks cannot be executed

Forced breaks cannot be executed if one of the following conditions is satisfied.

- Interrupts are disabled (DI)
- Interrupts issued for the INTP pin, which is used for communication between MINICUBE2 and the target device, are masked
- The alternate-function port corresponding to the INTP pin is not set to the input mode
- The external interrupt edge corresponding to the INTP pin is not set to the rising edge
- Standby mode is entered while standby release by a maskable interrupt is prohibited

(5) Flash self programming

If a space where the debug monitor program is allocated is rewritten by flash self programming, the debugger can no longer operate normally.

(6) Operation after reset

After an external pin reset or internal reset, the monitor program performs debug initialization processing. Consequently, the time from reset occurrence until user program execution differs from that in the actual device operation.

(7) Emulation of POC function

The POC function of the target device cannot be emulated. Make sure that the power to the target system is not shut down during debugging.

(8) Debugging with real machine running without using MINICUBE2

If debugging is performed with a real machine running, without using MINICUBE2, write the user program using the QB-Programmer. Programs downloaded by the debugger include the monitor program, and such a program malfunctions if it is not controlled via MINICUBE2.

5.3 Flash Programming

This section describes the system configuration and startup/shutdown procedure when flash programming is performed for the 78K0S Series using MINICUBE2.

5.3.1 Specifications of programming function

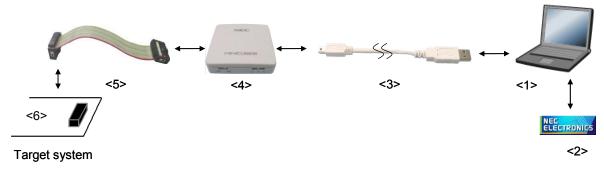

Table 5-5. Specifications of Programming Function

Functions	Specifications
Host interface	USB 2.0 (compatible with 1.1)
Target interface	UART
Target system voltage	2.7 to 5.5 V (depends on the target device)
Clock supply	8 MHz clock can be supplied
Power supply	3 or 5 V (maximum current rating: 100 mA)
Acquisition of device-specific information	Parameter file for NEC Electronics PG-FP4 is used
Security flag setting	Available
Standalone operation	Unavailable (must be connected to host machine)

5.3.2 System configuration

Figure 5-17 illustrates the system configuration for flash programming.

Figure 5-17. System Configuration for Flash Programming

<1> Host machine

Products with USB ports

<2> Software

Includes the QB-Programmer USB driver, parameter files, and so on.

Download these NEC Electronics software from the following website (ODS).

URL: http://www.necel.com/micro/ods/eng/index.html

- <3> USB cable (accessory)
- <4> MINICUBE2 (this product)
- <5> 16-pin target cable (accessory)
- <6> Target connector (sold separately)

5.3.3 System startup procedure

This section describes the system startup procedure. Observe the following order.

(1) Preparation and installation of software

The following software is required to perform flash programming. For details on preparation and installation of software, refer to the setup manual supplied with MINICUBE2.

- QB-Programmer
- USB driver
- Parameter file

(2) Switch setting

Set the mode select switch to "M1". Set the power select switch by referring to the following table.

Caution Do not change the switch setting while the USB cable is connected.

Table 5-6. Setting of Power Select Switch

Setting	Description	
3	3 V is supplied from MINICUBE2 to the target system Note.	
5	5 V is supplied from MINICUBE2 to the target system Note.	
Т	Power supply of the target system is used.	
	MINICUBE2 detects the power for the target system.	
	The detected power is also used as the power supply for the communication interface.	

Note The maximum rating of the current is 100 mA, so do not use MINICUBE2 with the target system with the higher current rating. The power is always supplied after MINICUBE2 is connected to the host machine.

(3) Connecting the target system

Connect MINICUBE2 to the target system as shown in Figure 5-18, **before the power to the target system is turned on**. When the power select switch is set to "T", the step of **(4) Connecting the USB cable** can be performed before this step.

Figure 5-18. Connecting MINICUBE2 to Target System

(4) Connecting the USB cable

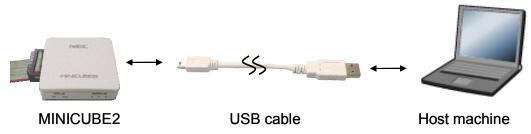

Connect MINICUBE2 to the host machine as shown in Figure 5-19, before the power to the target system is turned on.

When the power select switch is set to "T", the mode LED **flashes** white after connection.

When the power select switch is set to "3" or "5", the mode LED **glows** white after connection. The power is always supplied after MINICUBE2 is connected to the host machine with the USB cable.

Caution Do not change the switch setting while the USB cable is connected.

Figure 5-19. Connecting MINICUBE2 to Host Machine

(5) Applying power to target system

Turn on power to the target system. This step is not necessary if the power select switch is set to "3" or "5". The mode LED glows white after power application.

(6) QB-Programmer startup

Start the QB-Programmer from the Start menu of Windows. The mode LED glows green after QB-Programmer startup.

A series of basic operations after this step is described in the following section. For detailed usage of the QB-Programmer, refer to the **QB-Programmer User's Manual**.

5.3.4 Usage examples

This section describes a series of basic operations using the QB-Programmer, using the μ PD78F9234 as an example. The operations from execution of the [Autoprocedure (EPV)] command to programming for the target device are described. For other commands and their applications, refer to the QB-Programmer Programming GUI Operation User's Manual.

The conditions used for a series of operations in this section are as follows.

<Target system>

Target device: μ PD78F9234

Power supply voltage: 5 V (supplied from MINICUBE2)

Communication channel: UART

<MINICUBE2>

Switches: Mode select switch: M1

Power select switch: 5

<QB-Programmer>

Parameter file: 78F9234.PRM

Clock setting: 8 MHz (supplied from MINICUBE2)

Operation mode: chip

Program file: sample.hex

Command options: [Blank check before Erase] selected

[Checksum flag after Program] selected

(1) Setting of programming environment

Set the programming environment, following the steps <1> to <6> described below.

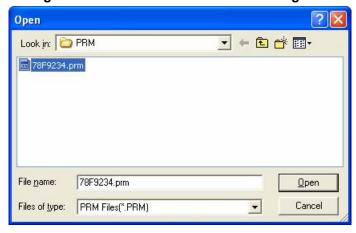

- <1> Click the [Device] menu on the menu bar and then click [Setup...].
- <2> The Device Setup dialog box appears, in which the [Standard] tab is active.

Figure 5-20. [Standard] Tab of Device Setup Dialog Box

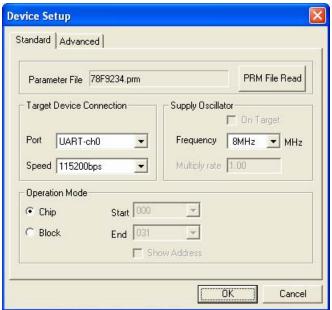

<3> Click the PRM File Read button to open the Parameter File Select dialog box. Select the parameter file for the target device and then click the Open button.

Figure 5-21. Parameter File Select Dialog Box

<4> Set the items in the [Target Device Connection], [Operation Mode] and [Supply Oscillator] areas, in accordance with your programming environment. The following figure shows an example.

Figure 5-22. [Standard] Tab of Device Setup Dialog Box After Setting

<5> Next, set the items in the [Command options] and [Security flag settings] areas, in accordance with your programming environment. The following figure shows an example.

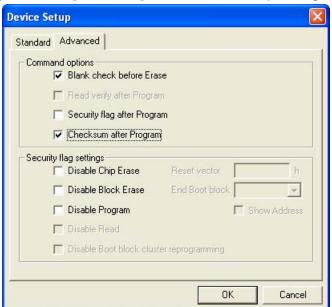

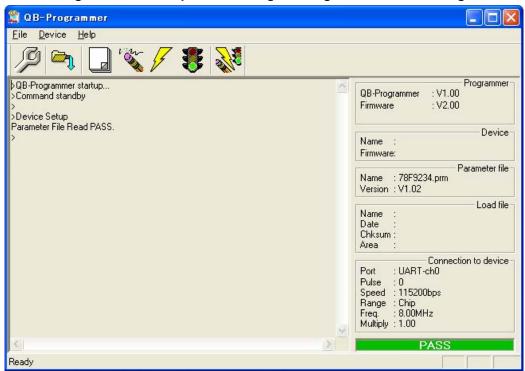

Figure 5-23. [Advanced] Tab of Device Setup Dialog Box

<6> By clicking the OK button, the programming environment is set and the Device Setup dialog box is closed. The main window appears as follows.

Figure 5-24. Completion of Programming Environment Setting

(2) Selection of program file

Select the program file, following the steps <1> to <3> described below.

- <1> Click the [File] menu on the menu bar and then click [Load...].
- <2> The program file select dialog box appears.

<3> Select the program file for the target device and then click the Open button.

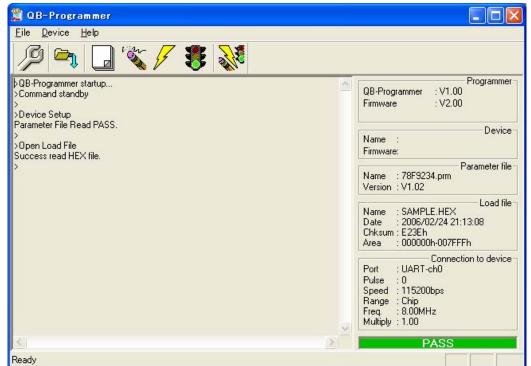

Figure 5-26. Completion of Program File Selection

(3) Execution of [Autoprocedure (EPV)] command

Click the [Device] menu on the menu bar and then click [Autoprocedure (EPV)].

The [Blank Check], [Erase] (if the flash memory in the target device is not blank), [Program], [Verify], and [Security] commands are executed for the target device sequentially. The mode LED on MINICUBE2 glows yellow during execution. When the command execution is completed normally, the mode LED glows green and the following window appears.

🚆 QB-Programmer File Device Help Programmer AutoProcedure(Epv) V1.00 QB-Programmer Blank check Chip: Not blank, Erase need. : V2.00 Firmware Erasing... Erase Chip: PASS Truncate the HEX File. Device Program Chip: 10% Name: UPD78F9234 Firmware: 0.00 20% 30% Parameter file Name : 78F9234.prm 40% 50% Version: V1.02 60% Load file 70% SAMPLE.HEX Name 80% 90% Date 2006/02/24 21:13:08 Chksum: F23Fh 100% 000000h-007FFFh Area PASS Device Checksum: 0x1842 QBP Checksum : 0x1842 Checksum compare: PASS Connection to device UART-ch0 Port Pulse 0 AutoProcedure(Epv) PASS Speed 115200bps Chip 8.00MHz Range Freq. Multiply : 1.00 PASS Ready

Figure 5-27. Completion of [Autoprocedure (EPV)] Command Execution

5.3.5 System shutdown procedure

Terminate flash programming and shutdown the system in the following order.

If the following order is not observed, the target system or MINICUBE2 may be damaged.

(1) Terminating the QB-Programmer

Terminate the QB-Programmer if you are not going to perform programming to other devices.

Remark When the QB-Programmer is terminated, the setting information is saved in the *qbp.ini* file. Due to this file, the same setting is maintained when the QB-Programmer is started the next time.

(2) Target system power shutdown

Shutdown the power supplied to the target system. This step is not necessary if the power select switch is set to "3" or "5".

(3) Unplugging the USB cable

Unplug the USB cable from MINICUBE2 or the host machine.

When the power select switch is set to "T", the step of (4) Unplugging the target cable can be performed before this step.

(4) Unplugging the target cable

Unplug the target cable from MINICUBE2 or the target system.

5.3.6 Cautions on flash programming

This section describes the cautions for flash programming. Be sure to read the following for the proper use of MINICUBE2.

- To improve the writing quality, fully understand, verify, and evaluate the following items before using MINICUBE2.
 - Circuits are designed as described in the user's manuals for the device and MINICUBE2.
 - The device, QB-Programmer and MINICUBE2 are used as described in each user's manual.
 - The power supplied to the target system is stable.

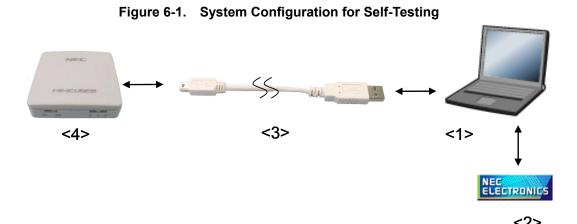

CHAPTER 6 SELF-TESTING

This section describes the method to perform self-testing with MINICUBE2.

The MINICUBE2 diagnostic tool can be used to find if the reason that the debugger does not operate normally derives from a MINICUBE2 defect or from other hardware

6.1 System Configuration

Figure 6-1 illustrates the system configuration for self-testing.

<1> Host machine

Products with USB ports

<2> Software

Includes the USB driver and MINICUBE2 diagnostic tool.

These software can be installed when an NEC Electronics debugger or QB-Programmer is installed.

Download these NEC Electronics software from the following website (ODS).

URL: http://www.necel.com/micro/ods/eng/index.html

- <3> USB cable (accessory)
- <4> MINICUBE2 (this product)

6.2 Self-Testing Procedure

(1) Preparation and installation of software

The following software is required to perform self-testing. For details on preparation and installation of software, refer to the setup manual supplied with MINICUBE2.

- MINICUBE2 diagnostic tool
- USB driver

(2) Switch setting

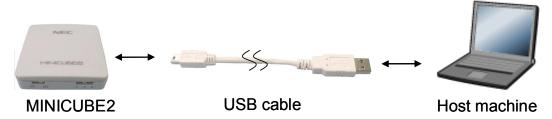

The mode select switch can be set to "M1" or "M2".

Set the power select switch to "3" or "5".

(3) Connecting the USB cable

Connect MINICUBE2 to the host machine **before connecting to the target system**. The mode LED glows white after connection.

Figure 6-2. Connecting MINICUBE2 to Host Machine

(4) Startup of MINICUBE2 diagnostic tool

Start the MINICUBE2 diagnostic tool.

If the MINICUBE2 diagnostic tool was installed when NEC Electronics software was installed, the diagnostic tool is registered on the Start menu as follows.

"NEC Electronics" → "MINICUBE Utilities" → "Vx.xx (version)"

For the operation after this step, refer to the user's manual for the MINICUBE2 diagnostic tool.

CHAPTER 7 FIRMWARE UPDATE

Firmware is a program embedded in the device for controlling MINICUBE2. The following can be implemented by updating firmware.

- · Addition of supported devices
- · Correction of restrictions

This chapter describes the method for checking firmware version, system configuration, and firmware update procedure. Note that MINICUBE2 may no longer operate if firmware is updated incorrectly.

7.1 System Configuration

Figure 7-1 illustrates the system configuration for updating firmware.

Figure 7-1. System Configuration for Firmware Update

4>
4>
1>
NEC

<1> Host machine

Products with USB ports

<2> Software

Includes the USB driver and MINICUBE2 diagnostic tool.

These software can be installed when an NEC Electronics debugger or QB-Programmer is installed.

Download these NEC Electronics software from the following website (ODS).

URL: http://www.necel.com/micro/ods/eng/index.html

<3> USB cable (accessory)

<4> MINICUBE2 (this product)

7.2 Firmware Update Procedure

(1) Preparation and installation of software

The following software is required to update firmware. For details on preparation and installation of software, refer to the setup manual supplied with MINICUBE2.

- MINICUBE2 diagnostic tool
- USB driver

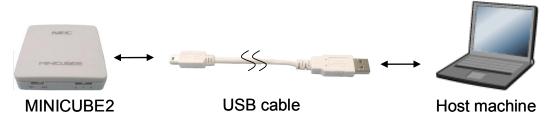

(2) Switch setting

The mode select switch and power select switch may be set to any position.

(3) Connecting the USB cable

Connect MINICUBE2 to the host machine **before connecting to the target system**. The mode LED glows white after connection.

Figure 7-2. Connecting MINICUBE2 to Host Machine

(4) Startup of MINICUBE2 diagnostic tool

Start the MINICUBE2 diagnostic tool.

If the MINICUBE2 diagnostic tool was installed when NEC Electronics software was installed, the diagnostic tool is registered on the Start menu as follows.

"NEC Electronics" → "MINICUBE Utilities" → "Vx.xx (version)"

For the operation after this step, refer to the user's manual for the MINICUBE diagnostic tool.

CHAPTER 8 REVISION HISTORY

Document Number	Issued on	Description
ZUD-CD-06-0018	March 20, 2006	1st edition
ZUD-CD-06-0018-1	April 24, 2006	Changes in conjunction with support of 78K0S
		- Addition of 78K0S Series setting to Table 2-1 (p. 13)
		- Addition of descriptions of 78K0S Series to Table 2-3 (p. 14)
		- Addition of CHAPTER 5 HOW TO USE MINICUBE2 WITH 78K0S
		SERIES (p. 97)
		Other changes
		- Addition of descriptions of H/S pin to 3.1 Target System Design (p. 17)
		- Addition of descriptions to (3) Resetting the target device by
		power-on clear (POC) only (p. 24)
		- Modification of coments and addresses in sample sources (p. 33)
		- Addition of (9) to (11) (p. 38)
		- Modification of OCD1B pin connection in Figures 4-5, 4-6, and 4-8 (pp.
		56, 57, 59)
		- Addition of (4) Resetting the target device by power-on clear (POC)
		only (p. 65)
		- Addition of (13) Emulation of POC function (p. 86)
