

### FEATURES

Improved Replacement for:  
INA117P and INA117KU

$\pm 270$  V Common-Mode Voltage Range

Input Protection to:

$\pm 500$  V Common Mode

$\pm 500$  V Differential

Wide Power Supply Range ( $\pm 2.5$  V to  $\pm 18$  V)

$\pm 10$  V Output Swing on  $\pm 12$  V Supply

1 mA Max Power Supply Current

### HIGH ACCURACY DC PERFORMANCE

3 ppm Max Gain Nonlinearity

20  $\mu\text{V}/^\circ\text{C}$  Max Offset Drift (AD629A)

10  $\mu\text{V}/^\circ\text{C}$  Max Offset Drift (AD629B)

10 ppm/ $^\circ\text{C}$  Max Gain Drift

### EXCELLENT AC SPECIFICATIONS

77 dB Min CMRR @ 500 Hz (AD629A)

86 dB Min CMRR @ 500 Hz (AD629B)

500 kHz Bandwidth

### APPLICATIONS

High Voltage Current Sensing

Battery Cell Voltage Monitor

Power Supply Current Monitor

Motor Control

Isolation

### FUNCTIONAL BLOCK DIAGRAM

### GENERAL DESCRIPTION

The AD629 is a difference amplifier with a very high input common-mode voltage range. It is a precision device that allows the user to accurately measure differential signals in the presence of high common-mode voltages up to  $\pm 270$  V.

The AD629 can replace costly isolation amplifiers in applications that do not require galvanic isolation. The device will operate over a  $\pm 270$  V common-mode voltage range and has inputs that are protected from common-mode or differential mode transients up to  $\pm 500$  V.

The AD629 has low offset, low offset drift, low gain error drift, as well as low common-mode rejection drift, and excellent CMRR over a wide frequency range.

## THEORY OF OPERATION

The AD629 is a unity gain differential-to-single-ended amplifier (Diff Amp) that can reject extremely high common-mode signals (in excess of 270 V with 15 V supplies). It consists of an operational amplifier (Op Amp) and a resistor network.

In order to achieve high common-mode voltage range, an internal resistor divider (Pin 3, Pin 5) attenuates the noninverting signal by a factor of 20. Other internal resistors (Pin 1, Pin 2, and the feedback resistor) restores the gain to provide a differential gain of unity. The complete transfer function equals:

$$V_{OUT} = V(+IN) - V(-IN)$$

Laser wafer trimming provides resistor matching so that common-mode signals are rejected while differential input signals are amplified.

The op amp itself, in order to reduce output drift, uses super beta transistors in its input stage. The input offset current and its associated temperature coefficient contribute no appreciable output voltage offset or drift. This has the added benefit of reducing voltage noise because the corner where  $1/f$  noise becomes dominant is below 5 Hz. In order to reduce the dependence of gain accuracy on the op amp, the open-loop voltage gain of the op amp exceeds 20 million, and the PSRR exceeds 140 dB.

<sup>2</sup>7" Tape and Reel of 1000 each

## CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the AD629 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

## APPLICATIONS

### Basic Connections

Figure 29 shows the basic connections for operating the AD629 with a dual supply. A supply voltage of between  $\pm 3$  V and  $\pm 18$  V is applied between Pins 7 and 4. Both supplies should be decoupled close to the pins using  $0.1 \mu\text{F}$  capacitors.  $10 \mu\text{F}$  electrolytic capacitors, also located close to the supply pins, may also be required if low frequency noise is present on the power supply. While multiple amplifiers can be decoupled by a single set of  $10 \mu\text{F}$  capacitors, each in amp should have its own set of  $0.1 \mu\text{F}$  capacitors so that the decoupling point can be located physically close to the power pins.

Figure 29. Basic Connections

The differential input signal, which will typically result from a load current flowing through a small shunt resistor, is applied to Pins 2 and 3 with the polarity shown in order to obtain a positive gain. The common-mode range on the differential input signal can range from  $-270$  V to  $+270$  V and the maximum differential range is  $\pm 13$  V. When configured as shown, the device operates as a simple gain-of-one differential-to-single-ended amplifier, the output voltage being the shunt resistance times the shunt current. The output is measured with respect to Pins 1 and 5.

Pins 1 and 5 (REF(-) and REF(+)) should be grounded for a gain of unity and should be connected to the same low impedance ground plane. Failure to do this will result in degraded common-mode rejection. Pin 8 is a no connect pin and should be left open.

### Single Supply Operation

Figure 30 shows the connections for operating the AD629 with a single supply. Because the output can swing to within only about 2 V of either rail, it is necessary to apply an offset to the output. This can be conveniently done by connecting REF(+) and REF(-) to a low impedance reference voltage (some analog-to-digital converters provide this voltage as an output), which is capable of sinking current. Thus, for a single supply of 10 V,  $V_{REF}$  might be set to 5 V for a bipolar input signal. This would allow the output to swing  $\pm 3$  V around the central 5 V reference voltage. Alternatively, for unipolar input signals,  $V_{REF}$  could be set to about 2 V, allowing the output to swing from +2 V (for a 0 V input) to within 2 V of the positive rail.

Figure 30. Operation with a Single Supply

Applying a reference voltage to REF(+) and REF(-) and operating on a single supply will reduce the input common-mode range of the AD629. The new input common-mode range depends upon the voltage at the inverting and noninverting inputs of the internal operational amplifier, labeled  $V_X$  and  $V_Y$  in Figure 30. These nodes can swing to within 1 V of either rail. So for a (single) supply voltage of 10 V,  $V_X$  and  $V_Y$  can range between 1 V and 9 V. If  $V_{REF}$  is set to 5 V, the permissible common-mode range is  $+85$  V to  $-75$  V. The common-mode voltage ranges can be calculated using the following equation.

$$V_{CM}(\pm) = 20 V_{X/Y}(\pm) - 19 V_{REF}$$

### System-Level Decoupling and Grounding

The use of ground planes is recommended to minimize the impedance of ground returns (and hence the size of dc errors). Figure 31 shows how to work with grounding in a mixed-signal environment, that is, with digital and analog signals present. In order to isolate low-level analog signals from a noisy digital environment, many data-acquisition components have separate analog and digital ground returns. All ground pins from mixed-signal components such as analog-to-digital converters should be returned through the “high quality” analog ground plane. This includes the digital ground lines of mixed-signal converters that should also be connected to the analog ground plane. This may seem to break the rule of keeping analog and digital grounds separate, but in general, there is also a requirement to keep the voltage difference between digital and analog grounds on a converter as small as possible (typically  $<0.3$  V). The increased noise, caused by the converter’s digital return currents flowing through the analog ground plane, will typically be negligible. Maximum isolation between analog and digital is achieved by connecting the ground planes back at the supplies. Note that Figure 31, as drawn, suggests a “star” ground system for the analog circuitry, with all ground lines being connected, in this case, to the ADC’s analog ground. However, when ground planes are used, it is sufficient to connect ground pins to the nearest point on the low impedance ground plane.

Figure 31. Optimal Grounding Practice for a Bipolar Supply Environment with Separate Analog and Digital Supplies

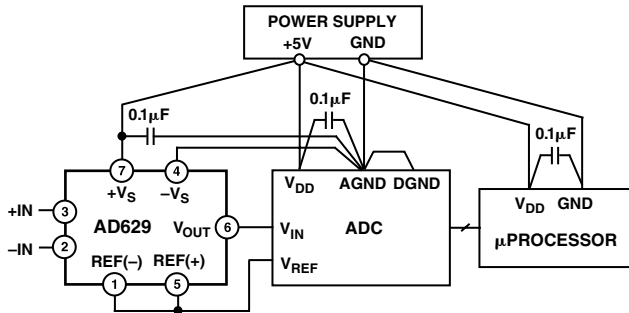

Figure 32. Optimal Ground Practice in a Single Supply Environment

If there is only a single power supply available, it must be shared by both digital and analog circuitry. Figure 32 shows how to minimize interference between the digital and analog circuitry. In this example, the ADC's reference is used to drive the AD629's REF(+) and REF(-) pins. This means that the reference must be capable of sourcing and sinking a current equal to  $V_{CM}/200\text{ k}\Omega$ . As in the previous case, separate analog and digital ground planes should be used (reasonably thick traces can be used as an alternative to a digital ground plane). These ground planes should be connected at the power supply's ground pin. Separate traces (or power planes) should be run from the power supply to the supply pins of the digital and analog circuits. Ideally, each device should have its own power supply trace, but these can be shared by a number of devices as long as a single trace is not used to route current to both digital and analog circuitry.

### Using a Large Sense Resistor

Insertion of a large shunt resistance across the input Pins 2 and 3 will imbalance the input resistor network, introducing a common-mode error. The magnitude of the error will depend on the common-mode voltage and the magnitude of  $R_{SHUNT}$ . Table I

shows some sample error voltages generated by a common-mode voltage of 200 V dc with shunt resistors from 20  $\Omega$  to 2000  $\Omega$ . Assuming that the shunt resistor has been selected to utilize the full  $\pm 10\text{ V}$  output swing of the AD629, the error voltage becomes quite significant as  $R_{SHUNT}$  increases.

Table I. Error Resulting from Large Values of  $R_{SHUNT}$  (Uncompensated Circuit)

$R_S$ ( $\Omega$ )	Error $V_{OUT}$ (V)	Error Indicated (mA)
20	0.01	0.5
1000	0.498	0.498
2000	1	0.5

If it is desired to measure low current or current near zero in a high common-mode environment, an external resistor equal to the shunt resistor value may be added to the low impedance side of the shunt resistor as shown in Figure 33.

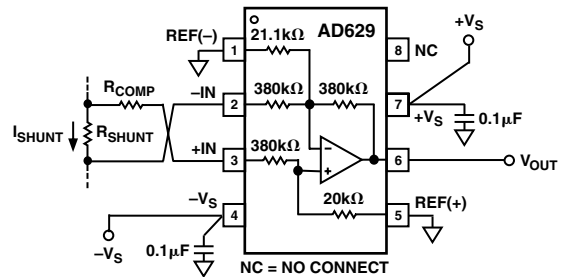

Figure 33. Compensating for Large Sense Resistors

### Output Filtering

A simple 2-pole low-pass Butterworth filter can be implemented using the OP177 at the output of the AD629 to limit noise at the output, as shown in Figure 34. Table II gives recommended component values for various corner frequencies, along with the peak-to-peak output noise for each case.

Figure 34. Filtering of Output Noise Using a 2-Pole Butterworth Filter

Table II. Recommended Values for 2-Pole Butterworth Filter

Corner Frequency	R1	R2	C1	C2	Output Noise (p-p)
No Filter					3.2 mV
50 kHz	2.94 k $\Omega$ $\pm$ 1%	1.58 k $\Omega$ $\pm$ 1%	2.2 nF $\pm$ 10%	1 nF $\pm$ 10%	1 mV

# AD629

## Output Current and Buffering

The AD629 is designed to drive loads of 2 kΩ to within 2 V of the rails, but can deliver higher output currents at lower output voltages (see Figure 15). If higher output current is required, the AD629's output should be buffered with a precision op amp such as the OP113 as shown in Figure 35. This op amp can swing to within 1 V of either rail while driving a load as small as 600 Ω.

Figure 35. Output Buffering Application

## A Gain of 19 Differential Amplifier

While low level signals can be connected directly to the -IN and +IN inputs of the AD629, differential input signals can also be connected as shown in Figure 36 to give a precise gain of 19. However, large common-mode voltages are no longer permissible. Cold junction compensation can be implemented using a temperature sensor such as the AD590.

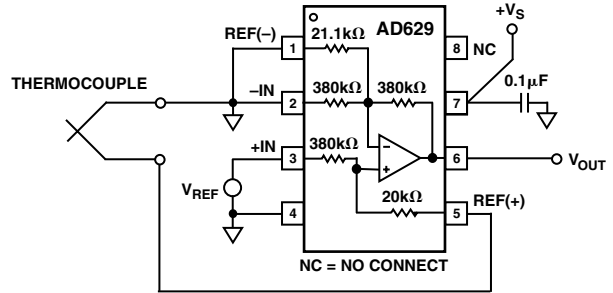

Figure 36. A Gain of 19 Thermocouple Amplifier

## Error Budget Analysis Example 1

In the dc application below, the 10 A output current from a device with a high common-mode voltage (such as a power supply or current-mode amplifier) is sensed across a 1 Ω shunt resistor (Figure 37). The common-mode voltage is 200 V, and the resistor terminals are connected through a long pair of lead wires located in a high-noise environment, for example, 50 Hz/60 Hz 440 V ac power lines. The calculations in Table III assume an induced noise level of 1 V at 60 Hz on the leads, in addition to a full-scale dc differential voltage of 10 V. The error budget table quantifies the contribution of each error source. Note that the dominant error source in this example is due to the dc common-mode voltage.

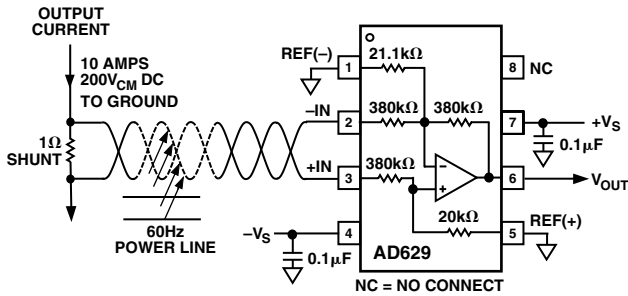

Figure 37. Error Budget Analysis Example 1.  $V_{IN} = 10\text{ V}$  Full-Scale,  $V_{CM} = 200\text{ V DC}$ ,  $R_{SHUNT} = 1\ \Omega$ ,  $1\text{ V p-p } 60\text{ Hz}$  Power-Line Interference

**Error Budget Analysis Example 2**

This application is similar to the previous example except that the sensed load current is from an amplifier with an ac common-mode component of  $\pm 100\text{ V}$  (frequency =  $500\text{ Hz}$ ) present on the shunt (Figure 38). All other conditions are the same as

before. Note that the same kind of power line interference can happen as detailed in Example 1. However, the ac common-mode component of  $200\text{ V p-p}$  coming from the shunt is much larger than the interference of  $1\text{ V p-p}$ , so that this interference component can be neglected.

Figure 38. Error Budget Analysis Example 2.  $V_{IN} = 10\text{ V}$  Full-Scale,  $V_{CM} = \pm 100\text{ V at } 500\text{ Hz}$ ,  $R_{SHUNT} = 1\ \Omega$

Offset Voltage	$(0.001\text{ V} \div 10\text{ V}) \times 10^6$	$(0.002\text{ V} \div 10\text{ V}) \times 10^6$	100	200
Total Accuracy Error:			600	700
<b>TEMPERATURE DRIFT (<math>85^\circ\text{C}</math>)</b>				
Gain	$10\text{ ppm}/^\circ\text{C} \times 60^\circ\text{C}$	$10\text{ ppm}/^\circ\text{C} \times 60^\circ\text{C}$	600	600
Offset Voltage	$(20\ \mu\text{V}/^\circ\text{C} \times 60^\circ\text{C}) \times 10^6/10\text{ V}$	$(40\ \mu\text{V}/^\circ\text{C} \times 60^\circ\text{C}) \times 10^6/10\text{ V}$	120	240
Total Drift Error:			720	840
<b>RESOLUTION</b>				
Noise, Typ, 0.01–10 Hz, $\mu\text{V p-p}$	$15\ \mu\text{V} \div 10\text{ V} \times 10^6$	$25\ \mu\text{V} \div 10\text{ V} \times 10^6$	2	3
CMR @ 60 Hz	$(141 \times 10^{-6} \times 1\text{ V}) \div 10\text{ V} \times 10^6$	$(500 \times 10^{-6} \times 1\text{ V}) \div 10\text{ V} \times 10^6$	14	50
Nonlinearity	$(10^{-5} \times 10\text{ V}) \div 10\text{ V} \times 10^6$	$(10^{-5} \times 10\text{ V}) \div 10\text{ V} \times 10^6$	10	10
AC CMR @ 500 Hz	$(141 \times 10^{-6} \times 200\text{ V}) \div 10\text{ V} \times 10^6$	$(500 \times 10^{-6} \times 200\text{ V}) \div 10\text{ V} \times 10^6$	2,820	10,000
Total Resolution Error:			2,846	10,063
Total Error:			4,166	11,603

## OUTLINE DIMENSIONS

Dimensions shown in inches and (mm).

### 8-Lead Plastic DIP (N-8)

### 8-Lead SOIC (SO-8)
