**DESCRIPTION**

The M48Z128/Y/V ZEROPOWER<sup>®</sup> RAM is a 128 Kbit x 8 non-volatile static RAM organized as 131,072 words by 8 bits. The device combines an internal lithium battery, a CMOS SRAM and a control circuit in a plastic, 32-pin DIP module. This solution is available in two special packages to provide a highly integrated battery backed-up memory solution.

The M48Z128/Y/V is a non-volatile pin and function equivalent to any JEDEC standard 128K x 8 SRAM. It also easily fits into many ROM, EPROM, and EEPROM sockets, providing the non-volatility of PROMs without any requirement for special WRITE timing or limitations on the number of WRITES that can be performed. The 32-pin, 600mil DIP Module houses the M48Z128/Y/V silicon with a long life lithium button cell in a single package.

For surface-mount environments ST provides an equivalent SMT solution consisting of a 28-pin, 330mil SOIC NVRAM SUPERVISOR (M40Z300/

W) and a 32-pin, (TSOP, 8 x 20mm) 1Mb LPSRAM. Both 5V and 3V versions are available (see Table 2., page 6).

The 28-pin, 330mil SOIC provides sockets with gold plated contacts at both ends for direct connection to a separate SNAPHAT<sup>®</sup> housing containing the battery.

The unique design allows the SNAPHAT battery package to be mounted on top of the SOIC package after the completion of the surface-mount process. Insertion of the SNAPHAT housing after reflow prevents potential battery damage due to the high temperatures required for device surface-mounting. The SNAPHAT housing is keyed to prevent reverse insertion.

The SNAPHAT battery package is shipped separately in plastic anti-static tubes or in Tape & Reel form. The part number is "M4Zxx-BR00SH" (see Table 17., page 19).

## OPERATING MODES

The M48Z128/Y/V also has its own Power-fail Detect circuit. The control circuitry constantly monitors the single  $V_{CC}$  supply for an out of tolerance condition. When  $V_{CC}$  is out of tolerance, the circuit write protects the SRAM providing a high degree

of data security in the midst of unpredictable system operation brought on by low  $V_{CC}$ . As  $V_{CC}$  falls below the switchover voltage ( $V_{SO}$ ), the control circuitry connects the battery which maintains data until valid power returns.

**Table 3. Operating Modes**

Mode	$V_{CC}$	$\bar{E}$	$\bar{G}$	$\bar{W}$	DQ0-DQ7	Power

Deselect	$V_{SO}$ to $V_{FD}(\min)^{(1)}$	X	X	X	High-Z	CMOS Standby
Deselect	$V_{SO}^{(1)}$	X	X	X	High-Z	Battery Back-up Mode

Note: X =  $V_{IH}$  or  $V_{IL}$ ;  $V_{SO}$  = Battery Back-up Switchover Voltage.

1. See Table 11., page 14 for details.

### READ Mode

The M48Z128/Y/V is in the READ Mode whenever  $\bar{W}$  (WRITE Enable) is high and  $\bar{E}$  (Chip Enable) is low. The device architecture allows ripple-through access of data from eight of 1,048,576 locations in the static storage array. Thus, the unique address specified by the 17 address inputs defines which one of the 131,072 bytes of data is to be accessed. Valid data will be available at the Data I/O pins within Address Access time ( $t_{AVQV}$ ) after the last address input signal is stable, providing that the  $\bar{E}$  and  $\bar{G}$  (Output Enable) access times are also sat-

isfied. If the  $\bar{E}$  and  $\bar{G}$  access times are not met, valid data will be available after the later of Chip Enable Access time ( $t_{GLQV}$ ) or Output Enable Access Time ( $t_{GLQV}$ ). The state of the eight three-state Data I/O signals is controlled by  $\bar{E}$  and  $\bar{G}$ . If the outputs are activated before  $t_{AVQV}$ , the data lines will be driven to an indeterminate state until  $t_{AVQV}$ . If the address inputs are changed while  $\bar{E}$  and  $\bar{G}$  remain low, output data will remain valid for Output Data Hold time ( $t_{AXQX}$ ) but will go indeterminate until the next Address Access.

2.  $C_L = 5\text{pF}$ .

**WRITE Mode**

The M48Z128/Y/V is in the WRITE Mode whenever  $\overline{W}$  and  $\overline{E}$  are active. The start of a WRITE is referenced from the latter occurring falling edge of  $\overline{W}$  or  $\overline{E}$ . A WRITE is terminated by the earlier rising edge of  $\overline{W}$  or  $\overline{E}$ .

The addresses must be held valid throughout the cycle.  $\overline{E}$  or  $\overline{W}$  must return high for minimum of  $t_{EHAX}$  from  $\overline{E}$  or  $t_{WHAX}$  from  $\overline{W}$  prior to the initiation

of another READ or WRITE cycle. Data-in must be valid  $t_{DVWH}$  prior to the end of WRITE and remain valid for  $t_{WHDX}$  or  $t_{EHDX}$  afterward.  $\overline{G}$  should be kept high during WRITE cycles to avoid bus contention; although, if the output bus has been activated by a low on  $\overline{E}$  and  $\overline{G}$ , a low on  $\overline{W}$  will disable the outputs  $t_{WLQZ}$  after  $\overline{W}$  falls.

2. C<sub>L</sub> = 5pF.

3. If  $\bar{E}$  goes low simultaneously with  $\bar{W}$  going low, the outputs remain in the high impedance state.

### Data Retention Mode

With valid  $V_{CC}$  applied, the M48Z128/Y/V operates as a conventional BYTEWIDE™ static RAM. Should the supply voltage decay, the RAM will automatically power-fail deselect, write protecting itself  $t_{WP}$  after  $V_{CC}$  falls below  $V_{PFD}$ . All outputs become high impedance, and all inputs are treated as “Don't care.”

If power fail detection occurs during a valid access, the memory cycle continues to completion. If the memory cycle fails to terminate within the time  $t_{WP}$ , write protection takes place. When  $V_{CC}$  drops below  $V_{SO}$ , the control circuit switches power to the internal energy source which preserves data.

The internal coin cell will maintain data in the M48Z128/Y/V after the initial application of  $V_{CC}$  for an accumulated period of at least 10 years when  $V_{CC}$  is less than  $V_{SO}$ . As system power returns and  $V_{CC}$  rises above  $V_{SO}$ , the battery is disconnected, and the power supply is switched to external  $V_{CC}$ . Write protection continues for  $t_{ER}$  after  $V_{CC}$  reaches  $V_{PFD}$  to allow for processor stabilization. After  $t_{ER}$ , normal RAM operation can resume.

For more information on Battery Storage Life refer to the Application Note AN1012.

### $V_{CC}$ Noise And Negative Going Transients

$I_{CC}$  transients, including those produced by output switching, can produce voltage fluctuations, resulting in spikes on the  $V_{CC}$  bus. These transients can be reduced if capacitors are used to store energy which stabilizes the  $V_{CC}$  bus. The energy stored in the bypass capacitors will be released as low going spikes are generated or energy will be absorbed when overshoots occur. A ceramic bypass capacitor value of  $0.1\mu\text{F}$  (see Figure 10.) is recommended in order to provide the needed filtering.

In addition to transients that are caused by normal SRAM operation, power cycling can generate negative voltage spikes on  $V_{CC}$  that drive it to values below  $V_{SS}$  by as much as one volt. These negative spikes can cause data corruption in the SRAM while in battery backup mode. To protect from these voltage spikes, ST recommends connecting a schottky diode from  $V_{CC}$  to  $V_{SS}$  (cathode connected to  $V_{CC}$ , anode to  $V_{SS}$ ). (Schottky diode 1N5817 is recommended for through hole and MBRS120T3 is recommended for surface-mount).

## MAXIMUM RATING

Stressing the device above the rating listed in the “Absolute Maximum Ratings” table may cause permanent damage to the device. These are stress ratings only and operation of the device at these or any other conditions above those indicated in the Operating sections of this specification is

not implied. Exposure to Absolute Maximum Rating conditions for extended periods may affect device reliability. Refer also to the STMicroelectronics SURE Program and other relevant quality documents.
