## FEATURES

## Low noise

Input voltage noise: $0.85 \mathrm{nV} / \sqrt{ } \mathrm{Hz}$
Current noise: $\mathbf{2 . 0} \mathbf{~ p A / \sqrt { H z }}$
High speed
200 MHz bandwidth ( $\mathrm{G}=12.04 \mathrm{~dB}$ )
295 V/ $\mu \mathrm{s}$ slew rate
Selectable gain
$\mathrm{G}=12.04 \mathrm{~dB}(\times 4)$
$\mathrm{G}=18.06 \mathrm{~dB}(\times 8)$
$\mathrm{G}=21.58 \mathrm{~dB}(\times 12)$
G $=24.08 \mathrm{~dB}(\times 16)$
Active input impedance matching
Integrated input clamp diodes
Single-ended input, differential output
Supply range: 4.5 V to 5.5 V
Low power: $60 \mathrm{~mW} /$ channel

## APPLICATIONS

CW Doppler ultrasound front ends
Low noise preamplification
Predriver for I/Q demodulators and phase shifters
Wideband analog-to-digital drivers

## GENERAL DESCRIPTION

The AD8432 is a dual-channel, low power, ultralow noise amplifier with selectable gain and active impedance matching. Each channel has a single-ended input, differential output, and integrated input clamps. By pin strapping the gain setting pins, four accurate gains of $\mathrm{G}=12.04 \mathrm{~dB}, 18.06 \mathrm{~dB}, 21.58 \mathrm{~dB}$, and 24.08 dB ( $\times 4, \times 8, \times 12$, and $\times 16$, respectively) are possible. A bandwidth of 200 MHz at $\mathrm{G}=12.04 \mathrm{~dB}$ makes this amplifier well suited for many high speed applications.

The exceptional noise performance of the AD8432 is made possible by the active impedance matching. Using a feedback network, the input impedance of the amplifiers can be adjusted to match the signal source impedance without compromising the noise performance. Impedance matching and low noise in the AD8432 allow designers to create wider dynamic range systems that are able to detect even very low level signals.

Figure 1.

The AD8432 achieves $0.85 \mathrm{nV} / \sqrt{ } \mathrm{Hz}$ input-referred voltage noise for a gain of 12.04 dB . The AD8432's ultralow noise, low distortion, gain accuracy, and channel-to-channel matching are ideal for high performance ultrasound systems and for processing I/Q demodulator signals.
The AD8432 operates on a single supply of 5 V at 24 mA . It is available in a $4 \mathrm{~mm} \times 4 \mathrm{~mm}, 24$-lead LFSCP. The LFCSP features an exposed paddle that provides a low thermal resistance path to the PCB, which enables more efficient heat transfer and increases reliability. The operating temperature range is $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$.

## ABSOLUTE MAXIMUM RATINGS

Table 2.

| Parameter | Rating |
| :--- | :--- |
| Voltage |  |
| $\quad$ Supply Voltage | 5.5 V |
| $\quad$ Input Voltage | 0 V to VPS |
| Power Dissipation | 120 mW |
| Temperature |  |
| $\quad$ Operating Temperature | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ |
| $\quad$ Storage Temperature | $-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$ |
| Package Glass Transition Temperature $\left(\mathrm{T}_{\mathrm{G}}\right)$ | $150^{\circ} \mathrm{C}$ |
| Lead Temperature (Soldering, 60 sec ) | $300^{\circ} \mathrm{C}$ |

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## THERMAL RESISTANCE

$\theta_{\text {IA }}$ is specified for the worst-case conditions, that is, a device soldered in a circuit board for surface-mount packages. The $\theta_{\text {IA }}$ value in Table 3 assumes a 4-layer JEDEC standard board with zero airflow.

Table 3. Thermal Resistance ${ }^{1}$

| Parameter | $\boldsymbol{\theta}_{\text {JA }}$ | $\boldsymbol{\theta}_{\text {JC }}$ | $\boldsymbol{\theta}_{\text {JB }}$ | $\boldsymbol{\Psi}_{\text {JT }}$ | Unit |
| :--- | :--- | :--- | :--- | :--- | :--- |
| 40-Lead LFCSP | 57.9 | 11.2 | 35.9 | 1.1 | ${ }^{\circ} \mathrm{C} / \mathrm{W}$ |

[^0]
## MAXIMUM POWER DISSIPATION

The maximum safe power dissipation for the AD8432 is limited by the associated rise in junction temperature $\left(\mathrm{T}_{\mathrm{J}}\right)$ on the die. At approximately $150^{\circ} \mathrm{C}$, which is the glass transition temperature, the properties of the plastic change. Even temporarily exceeding this temperature limit may change the stresses that the package exerts on the die, permanently shifting the parametric performance of the amplifiers. Exceeding a temperature of $150^{\circ} \mathrm{C}$ for an extended period can cause changes in silicon devices, potentially resulting in a loss of functionality.

## ESD CAUTION

|  | ESD (electrostatic discharge) sensitive device. <br> Charged devices and circuit boards can discharge <br> without detection. Although this product features <br> patented or proprietary protection circuitry, damage <br> may occur on devices subjected to high energy ESD. <br> Therefore, proper ESD precautions should be taken to <br> avoid performance degradation or loss of functionality. |

## AD8432

## THEORY OF OPERATION

## LOW NOISE AMPLIFIER (LNA)

The AD8432 is a dual-channel, ultralow noise amplifier with integrated pin-strappable, gain-setting resistors. The resistors can be externally connected to achieve differential gains of $12.04 \mathrm{~dB}, 18.06 \mathrm{~dB}, 21.58 \mathrm{~dB}$, and $24.08 \mathrm{~dB}(\times 4, \times 8, \times 12$, and $\times 16$, respectively). A simplified schematic of an LNA is shown in Figure 65.

The LNA is driven with a single-ended input and measured differentially at the output. The inverting input INL must be ac-coupled to ground through a capacitor for proper operation. The LNA cannot be driven differentially due to the asymmetry of the internal gain setting resistors. The gain from the inverting input INL to the single-ended output (OPH or OPL) does not match the gain from the noninverting input INH to the singleended output.
The AD8432 inputs have a dc bias voltage of 3.25 V , which is generated internally. The inputs must be ac-coupled through a series capacitor to maintain the dc bias level of the inputs. Likewise, the AD8432 outputs have a dc bias voltage of 2.5 V . An ac coupling capacitor in series with each single-ended output is recommended to prevent improper loading of the outputs. The AD8432 inputs have a dc bias voltage of 3.25 V , which is generated internally. The inputs must be ac-coupled through a series capacitor to maintain the dc bias level of the inputs (see CINL and CINH in Figure 65).
The AD8432 supports a differential output voltage of 4.8 V p-p for the common-mode output voltage of 2.5 V . Therefore, for a

| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 12.04 | 6.02 | 200 | 12 | 12 | Connect <br> GMH to GOH | Connect <br> GOH to OPH | 24 | Connect <br> GML to GOL | Connect <br> GOL to OPL |
| 18.06 | 12.04 | 90 | 12 | 12 | 24 | Connect <br> GOH to OPH | 24 | 24 | Connect <br> GOL to OPL |
| 21.58 | 15.56 | 50 | 12 | 12 | Connect <br> GMH to GOH | 48 | 24 | Connect <br> GML to GOL | 48 |
| 24.08 | 18.06 | 32 | 12 | 12 | 24 | 48 | 24 | 24 | 48 |

The single-ended gain from INH to OPH (see Figure 65) is defined as

$$
G_{O P H-I N H}=\frac{R_{G 1}+R_{G 2}+R_{G 3}+R_{G 4}}{R_{G 1}}
$$

The single-ended gain from INH to OPL is defined as

$$
G_{O P L-I N H}=-\frac{R_{G 5}+R_{G 6}+R_{G 7}}{R_{G 1}}
$$

The values of the seven gain resistors were chosen so that both single-ended gains are equal. For example, to set a gain of $12.04 \mathrm{~dB}(\mathrm{G}=\times 4)$ differentially, the gain from INH to each output ( $\mathrm{OPH}, \mathrm{OPL}$ ) should be $6.02 \mathrm{~dB}(\mathrm{G}=\times 2)$.
INH to OPH: For $\mathrm{R}_{\mathrm{G} 1}=\mathrm{R}_{\mathrm{G} 2}=\mathrm{R}_{\mathrm{G}}$, then

$$
G_{O P H-I N H}=\frac{R_{G 1}+R_{G 2}}{R_{G 1}}=\frac{2 \times R_{G}}{R_{G}}=2
$$

INH to OPL: For $R_{G 1}=R_{G}$ and $R_{G 5}=2 \times R_{G}$, then

$$
G_{O P L-I N H}=-\frac{R_{G 5}}{R_{G 1}}=-\frac{2 \times R_{G}}{R_{G}}=-2
$$

## ACTIVE INPUT RESISTANCE MATCHING

The AD8432 reduces noise and optimizes signal power transfer by using active input termination to perform signal source resistance matching.
The primary purpose of input impedance matching is to optimize the input signal power transfer. With resistive termination, the input noise increases due to the thermal noise of the terminating resistor and the increased contribution of the input voltage noise generator of the LNA. With active impedance matching, however, the contributions of both are smaller than they are for resistive termination by a factor of $1 /(1+1 / 2 \mathrm{LNA})$ gain. The noise figure (NF) for the three terminating schemes is shown in Figure 67.

To achieve this active impedance match, connect a feedback resistor, $R_{F B}$, between the INH and OPL (see Figure 66). $\mathrm{R}_{\mathrm{IN}}$ is given in Equation 1, where G/2 is the single-ended gain.

$$
\begin{equation*}
R_{I N}=\frac{R_{F B}}{1+\frac{G}{2}} \tag{1}
\end{equation*}
$$

In addition, to further reduce the input resistance, there is an internal resistance of $6.2 \mathrm{k} \Omega$ in parallel with the source resistance, such that

$$
\begin{equation*}
R_{I N}=\frac{R_{F B}}{1+\frac{G}{2}} \| R_{I N T E R N A L} \tag{2}
\end{equation*}
$$

Equation 3 should be used to calculate $\mathrm{R}_{\mathrm{FB}}$ accurately for a desired input resistance and single-ended gain. Refer to Table 6 for calculated results for $R_{F B}$ for several input resistance and gain combinations.

$$
\begin{equation*}
\Rightarrow R_{F B}=\frac{R_{I N}\left(1+\frac{G}{2}\right)}{1-\frac{R_{I N}}{R_{\text {INTERNAL }}}}, R_{\text {INTERNAL }}=6.2 \mathrm{k} \Omega \tag{3}
\end{equation*}
$$

Figure 67. Noise Figure vs. Rs for Resistive, Active Match, and Unterminated Inputs

Figure 68. Noise Figure vs. Rs for Various Values of RiN, Actively Matched

The user must determine the level of matching accuracy desired and adjust $\mathrm{R}_{\mathrm{FB}}$ accordingly. The $\mathrm{R}_{\mathrm{FB}}$ and $\mathrm{C}_{\mathrm{FB}}$ network presents a load to OPL that OPH does not see. The user can add an identical load on OPH to improve slightly the distortion caused by this imbalance.

There is a feedback capacitor ( $C_{F B}$ ) in series with $R_{F B}$ (see Figure 65) because the dc levels of the positive output and the positive input are different. At higher frequencies, the value of the feedback capacitor must be considered.

The unterminated bandwidth $\left(\mathrm{R}_{\mathrm{FB}}=\infty\right)$ is 200 MHz . The AD8432 has a low input-referred voltage noise of $0.85 \mathrm{nV} / \sqrt{ } \mathrm{Hz}$ at the lowest gain, 12.04 dB (unterminated configuration). To achieve such low noise, the dual amplifier consumes 24 mA , resulting in a power consumption of 120 mW .

## APPLICATIONS INFORMATION

The AD8432 LNA provides precision gain and ultralow noise performance with minimal external components. Because it is a high performance part, care must be taken to ensure that it is configured optimally to attain the best performance and dynamic range for the system.

## TYPICAL SETUP

The internal bias circuitry of the AD8432 sets the input bias voltage at 3.25 V and the output bias voltage at 2.5 V . It is important to ac couple the inputs through a capacitor to maintain the internal dc bias levels. When active input termination is used ( $\mathrm{R}_{\mathrm{FB}}$ ), a decoupling capacitor $\left(\mathrm{C}_{\mathrm{FB}}\right)$ is required to isolate the input and output bias voltages of the LNA. A typical value for $C_{F B}$ is $0.1 \mu \mathrm{~F}$, but a smaller value capacitor is more appropriate at higher frequencies.

The unterminated input impedance of the AD8432 is $6.2 \mathrm{k} \Omega$. Any input resistance between $50 \Omega$ and $6.2 \mathrm{k} \Omega$ can be synthesized using active impedance matching.
At the lowest gain ( 12.04 dB ), the gain response exhibits some peaking at higher frequencies. A resistor-capacitor shunt network (RC) at the input (see RSHx and CSHx in Figure 69) is recommended to reduce gain peaking and enhance stability at higher frequencies.

Table 7 shows the recommended values of $\mathrm{R}_{\mathrm{FB}}, \mathrm{CSH}_{\mathrm{SH}}$, and $\mathrm{R}_{\mathrm{SH}}$ for all four gains and several input impedance combinations. The values for the $\mathrm{C}_{\text {sH }}$ and Rsh $^{\text {network are determined empirically }}$ and can be customized as needed to optimize performance. As $\mathrm{R}_{\text {IN }}$ increases, the value of $\mathrm{C}_{\text {SH }}$ diminishes, and for higher input impedance values, no capacitor may be required.

## I/Q DEMODULATION FRONT END

The AD8432 low noise amplifiers can be used to drive the differential RF inputs of the dual AD8333 or the quad AD8339 I/Q demodulators. The primary application for the AD8339 is phased array beamforming in medical ultrasound, specifically in CW Doppler processing. Other applications include phased array radar and smart antennas for mobile communications.

Figure 70. Block Diagram of AD8432 and AD8339 Application for Ultrasound Beamforming

Because of its low output noise and low distortion, the AD8432 ensures minimal degradation in dynamic range while amplifying the RF input signal. At the lowest gain of 12.04 dB , the AD8432 contributes only $3.4 \mathrm{nV} / \sqrt{ } \mathrm{Hz}$ output voltage noise.
Figure 70 shows a simplified block diagram of one channel of the AD8432 driving the AD8339. The AD8432 outputs can be connected directly to the AD8339 RF inputs through $20 \Omega$ resistors. A differential clock signal, 4 LO , which is applied to the

4LOP and 4LON pins of the AD8339, has a frequency $4 \times$ that of the RF inputs. The AD8339 downconverts the RF signals, generates quadrature, and phase-shifts the resultant I and Q signals.
The I and Q outputs of the AD8339 are current outputs. A transimpedance amplifier, such as the AD8021, processes the outputs and performs several functions, including the following:

- Current-to-voltage conversion
- Summation amplifier for multiple channels
- Active low-pass filter

In beamforming applications, the I and Q outputs of a number of receiver channels are summed, which increases the system dynamic range by $10 \log _{10}(\mathrm{~N})$, where N is the number of channels being summed. The external RC feedback network of the AD8021 is a 100 kHz low-pass filter as shown in Figure 70. See the AD8333 and AD8339 datasheets for more details on implementing I/Q demodulators.
Evaluation boards are available for the AD8432 and the AD8339 to facilitate system level design and testing. A detailed reference schematic of the setup is shown in Figure 71. The AD8432 is shown in this configuration with a gain of 12.04 dB , with unterminated inputs. If active termination is preferred, use an $\mathrm{R}_{\mathrm{FB}}$ and $\mathrm{C}_{\mathrm{FB}}$ network as discussed in the Theory of Operation section. The IND1/IND2 clamping diodes can be connected to IN1/IN2 to protect the LNA input from being overdriven.

Figure 71. Schematic of the AD8432 $(G=12.04 d B)$ and AD8339 Application for Ultrasound Beamforming

## DIFFERENTIAL-TO-SINGLE-ENDED CONVERSION

Some applications require the low noise and high dynamic range of the AD8432; however, they may also require a singleended output, rather than a differential output. The AD8129 or AD8130 differential receiver amplifier can be used for the differential-to-single-ended conversion of the AD8432 output, as shown in Figure 72.
The AD8129 is a low noise, high gain ( 10 or greater) amplifier intended for applications over very long cables, where signal attenuation is significant. The AD8130 is stable at a gain of 1 and can be used for applications where lower gains are required. The AD8129 and AD8130 have user-adjustable gain, set by the ratio of two resistors, to help compensate for losses in the transmission line.

A transformer or balun can also be used to convert the differential output of the AD8432 to a single-ended output. Transformers have lower distortion; however, care must be taken to properly match the impedance of the transformer. The test circuit for distortion measurements in Figure 58 uses an ADTT1-1 transformer to perform differential-to-single-ended conversion.

Figure 72. AD8432 Differential-to-Single-Ended Conversion Using the AD8129/AD8130 with Unity Gain

## EVALUATION BOARD

Figure 73 shows the AD8432 evaluation board, and the schematic diagram is shown in Figure 74. Using the board is a convenient and fast way to verify system design and assess the performance of the AD8432 under user-specific operating conditions. The board provides access to all LNA inputs, outputs, and gain setting pins. The board is shipped in a typical $\mathrm{G}=12.04 \mathrm{~dB}$ configuration but is designed to allow customization of the setup as required.
The AD8432-EVALZ requires a single 5 V power supply. An on-board switch (S1) allows VPS to drive the enable (ENB) input.

## GAIN SETTING

Headers (W5 to W12) are provided across the gain setting pins and can be shorted using jumpers to allow gain setting quickly and easily. Alternately, it is recommended to short the gain setting pins using surface-mount (0402), $0 \Omega$ resistors (R1 to R4, R9 to R12) that eliminate the small parasitic capacitances from longer trace lengths to the headers. As shipped, the evaluation board is configured for $\mathrm{G}=12.04 \mathrm{~dB}$ with these $0 \Omega$ resistors.

Table 8 outlines the resistors or headers that must be installed or shorted for each gain configuration.

Table 8. Gain Setting Using Resistors or Headers

|  |  |  |  | Gain (V/V) |  |  |  |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :---: |
| LNA1 |  | LNA2 |  | 4 | $\mathbf{8}$ | $\mathbf{1 2}$ | $\mathbf{1 6}$ |  |

${ }^{1} \mathrm{X}=$ shorting the indicated header or resistor.

Figure 73. Evaluation Board

## AD8432

## SCHEMATIC

Figure 74. Schematic

## POWER SUPPLY

The AD8432 should be powered by a single 5 V supply connected to the VPOS terminal. Separate supplies can be used for VPS1, VPS2, and ENB, or they can all be tied to VPOS by shorting the W3 and W4 headers and the S1 switch. Ferrite beads and decoupling capacitors are installed for isolation, protection, and power supply noise reduction.

## INPUT TERMINATION

Active input impedance matching can be realized by installing a feedback resistor ( $\mathrm{R}_{\mathrm{FB}}$ ), the value of which is determined by the gain and source impedance, as described in the Theory of Operation section. $\mathrm{C}_{\mathrm{FB}}$ provides the necessary ac coupling between the input and output when using active termination; a $0.1 \mu \mathrm{~F}$ capacitor value is recommended. The $\mathrm{R}_{\mathrm{FB}}$ and $\mathrm{C}_{\mathrm{FB}}$ network presents a load to OPL, and an equivalent load at OPH can be used to balance the differential output.

Input clamping diodes (IND1 and IND2) can be connected to the inputs by shorting the connection on the W1 and W2 headers. The diodes provide overvoltage protection to the input and enable faster overdrive recovery times, especially at the lowest gain ( 12.04 dB ).

## OUTPUT

The AD8432 evaluation board provides the space to configure the output loading conditions required by the user, by populating the given footprints (for example, RL1, RL2, C7, and C8). SMA connectors are available at the outputs, and space for a transformer is also available for differential-to-single-ended conversion.

The 4-pin headers, PRB3 and PRB4, are placed close to the AD8432, and they provide a way for monitoring the differential output or the single-ended output using a high impedance differential probe. The two inner pins of the headers are connected to OPL/OPH, and the two outer pins of the headers are connected to ground.

There are several footprints provided to install ac coupling capacitors at the outputs (C7 to C14). The AD8432 outputs are biased internally at 2.5 V . To maintain the dc bias level, use coupling capacitors between the outputs and the load.
